SPECIFICATION

Spectral Identification of New States of Hydrogen

R. L. Mills, Y. Lu, J. He, M. Nansteel, P. Ray, X. Chen, A. Voigt, B. Dhandapani BlackLight Power, Inc., 493 Old Trenton Road, Cranbury, NJ 08512

ABSTRACT

Novel emission lines with energies of $q \cdot 13.6 \, eV$ where q = 1, 2, 3, 4, 6, 7, 8, 9, or 11 were previously observed by extreme ultraviolet (EUV) spectroscopy recorded on microwave discharges of helium with 2% hydrogen [R. L. Mills, P. Ray, "Extreme Ultraviolet Spectroscopy of Helium-Hydrogen Plasma", J. Phys. D, Applied Physics, Vol. 36, (2003), pp. 1535-1542]. These lines matched H(1/p), fractional Rydberg states of atomic hydrogen wherein $n = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots, \frac{1}{p}$; $(p \le 137 \text{ is an integer})$ replaces the well known parameter n = integer in the

Rydberg equation for hydrogen excited states. Evidence supports that these states are formed by a resonant nonradiative energy transfer to He^+ acting as a catalyst. Ar^+ also serves as a catalyst to form H(1/p); whereas, krypton, xenon, and their ions serve as controls. H(1/p) may react with a proton and two H(1/p) may react to form $H_2(1/p)^{\dagger}$ and $H_2(1/p)$, respectively, that have vibrational and rotational energies that are p^2 times those of the species comprising uncatalyzed atomic hydrogen. A series of over twenty peaks in the 10-65 nm region emitted from lowpressure helium-hydrogen (90/10%) and argon-hydrogen (90/10%) microwave plasmas matched the energy spacing of 2^2 times the vibrational energy of H_2^+ with the series ending on the bond energy of $H_2(1/4)^{+}$. Rotational lines were observed in the 145-300 nm region from atmospheric pressure electron-beam excited argon-hydrogen plasmas. The unprecedented energy spacing of 4^2 times that of hydrogen established the internuclear distance as 1/4 that of H_2 and identified $H_2(1/4)$. $H_2(1/p)$ gas was isolated by liquefaction at liquid nitrogen temperature and by decomposition of compounds found to contain the corresponding hydride ions $H^{-}(1/p)$. The $H_2(1/p)$ gas was dissolved in $CDCl_3$ and characterized by 1H NMR. Considering solvent effects, singlet peaks upfield of H_2 were observed with a predicted integer spacing of 0.64 ppm at 3.47, 3.03, 2.18, 1.47, 0.85, and 0.22 ppm which matched the consecutive series $H_2(1/2)$, $H_1(1/3)$, $H_2(1/4)$, $H_3(1/5)$, $H_3(1/6)$, and $H_3(1/7)$, respectively. Excess power was absolutely measured from the helium-hydrogen plasma. For an input of 41.9 W, the total plasma power of the helium-hydrogen plasma measured by water bath calorimetry was 62.1 W corresponding to 20.2 W of excess power in 3 cm³. The excess power density and energy balance were high, 6.7 W/cm³ and -5.4 X 10⁴ kJ/mole H, (280 eV/H atom), respectively. In addition to power applications, battery and rocketry propellant reactions are proposed that may be transformational, and observed excited vibration-rotational levels of $H_2(1/4)$ could be the basis of a UV laser that could significantly advance photolithography.

Keywords: fractional-principal-quantum-level atomic and molecular hydrogen and hydrogen molecule ion, vibrational series, rotational series, LN-condensable hydrogen, NMR series, exothermic plasma catalysis reaction

I. Introduction

r۶

A. Theoretical Predictions

The basic spectral emission of pure helium and hydrogen light sources have been well known for about a century. Recently, however, unique vacuum ultraviolet (VUV) emission lines were found at predicted wavelengths and reported in numerous publications [1-5]. For example, extreme ultraviolet (EUV) spectroscopy was recorded on microwave discharges of helium with 2% hydrogen. Novel emission lines were observed with energies of $q \cdot 13.6 \, eV$, q = 1,2,3,7,9,11. or $q \cdot 13.6 \, eV$, q = 4,6,8 less $21.2 \, eV$ corresponding to inelastic scattering of these photons by helium atoms due to excitation of $He(1s^2)$ to $He(1s^12p^1)$. These strong emissions are not found in any single gas plasma, and cannot be assigned to the known emission of any species of the single gases studied such as H, H^- , H_2 , H_2^+ , H_3^+ , He, He_2^+ , and He_1^+ , known species of the mixture such as He_2^+ , HeH^+ , HeH, HHe_2^+ , and HHe_1^+ and He_1^- , or possible contaminants [1]. However the results can be explained by a novel catalytic reaction involving atomic hydrogen [1-5].

J. R. Rydberg showed that all of the spectral lines of atomic hydrogen were given by a completely empirical relationship:

$$\overline{v} = R \left(\frac{1}{n_f^2} - \frac{1}{n_i^2} \right) \tag{1}$$

where $R = 109,677 \text{ cm}^{-1}$, $n_f = 1,2,3,...$, $n_i = 2,3,4,...$ and $n_i > n_f$. Bohr, Schrödinger, and Heisenberg each developed a theory for atomic hydrogen that gave the energy levels in agreement with Rydberg's equation.

agreement with Rydberg's equation.

$$E_n = -\frac{e^2}{n^2 8 \pi \varepsilon_a a_H} = -\frac{13.598 \, eV}{n^2}$$
(2a)

$$n = 1, 2, 3, \dots$$
 (2b)

where e is the elementary charge, ε_o is the permittivity of vacuum, and a_H is the radius of the hydrogen atom. The excited energy states of atomic hydrogen are given by Eq. (2a) for n > 1 in Eq. (2b). The n = 1 state is the "ground" state for "pure" photon transitions (i.e. the n = 1 state can absorb a photon and go to an excited electronic state, but it cannot release a photon and go to a lower-energy electronic state). However, an electron transition from the ground state to a lower-energy state may be possible by a resonant nonradiative energy transfer such as multipole coupling or a resonant collision mechanism. Processes such as hydrogen molecular bond formation that occur without photons and that require collisions are common [6]. Also, some commercial phosphors are based on resonant nonradiative energy transfer involving multipole

coupling [7].

٠,

The theory reported previously [1-5, 8-13] predicts that atomic hydrogen may undergo a catalytic reaction with certain atoms, excimers, and ions which provide a reaction with a net enthalpy of an integer multiple of the potential energy of atomic hydrogen, $E_h = 27.2 \ eV$ where E_h is one hartree. Specific species (e.g. He^+ , Ar^+ , and K) identifiable on the basis of their known electron energy levels are required to be present in plasmas with atomic hydrogen to catalyze the process. In contrast, species such as atoms or ions of Kr or Xe do not fulfill the catalyst criterion—a chemical or physical process with an enthalpy change equal to an integer multiple of E_h that is sufficiently reactive with atomic hydrogen under reaction conditions. The reaction involves a nonradiative energy transfer followed by $q \cdot 13.6 \ eV$ emission or $q \cdot 13.6 \ eV$ transfer to H to form extraordinarily hot, excited-state H [11-17] and a hydrogen atom that is lower in energy than unreacted atomic hydrogen that corresponds to a fractional principal quantum number. That is

$$n = \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \dots, \frac{1}{p}; \quad p \le 137 \text{ is an integer}$$
 (2c)

replaces the well known parameter n = integer in the Rydberg equation for hydrogen excited states. The n = 1 state of hydrogen and the $n = \frac{1}{\text{integer}}$ states of hydrogen are nonradiative, but

a transition between two nonradiative states, say n = 1 to n = 1/2, is possible via a nonradiative energy transfer. Thus, a catalyst provides a net positive enthalpy of reaction of $m \cdot 27.2 \, eV$ (i.e. it resonantly accepts the nonradiative energy transfer from hydrogen atoms and releases the energy to the surroundings to affect electronic transitions to fractional quantum energy levels). As a consequence of the nonradiative energy transfer, the hydrogen atom becomes unstable and emits further energy until it achieves a lower-energy nonradiative state having a principal energy level given by Eqs. (2a) and (2c).

Prior related studies that support the possibility of a novel reaction of atomic hydrogen which produces hydrogen in fractional quantum states that are at lower energies than the traditional "ground" (n = 1) state include extreme ultraviolet (EUV) spectroscopy [1-5, 10-13, 16-27], characteristic emission from catalysts and the hydride ion products [12-13, 18-20, 22-23], lower-energy hydrogen emission [1-5], chemically formed plasmas [10-13, 18-23], Balmer α line broadening [1, 2, 11-18, 20, 22-23, 25-26], population inversion of H lines [22-25], elevated electron temperature [14-16, 26], anomalous plasma afterglow duration [21], power generation [2, 4, 16, 26], and analysis of novel chemical compounds [28-30].

H(1/p) may react with a proton and two H(1/p) may react to form $H_2(1/p)^+$ and $H_2(1/p)$, respectively. The hydrogen molecular ion and molecular charge and current density functions, bond distances, and energies were solved previously [9] from the Laplacian in

ellipsoidal coordinates with the constraint of nonradiation.

$$(\eta - \zeta)R_{\xi}\frac{\partial}{\partial \xi}(R_{\xi}\frac{\partial \phi}{\partial \xi}) + (\zeta - \xi)R_{\eta}\frac{\partial}{\partial \eta}(R_{\eta}\frac{\partial \phi}{\partial \eta}) + (\xi - \eta)R_{\zeta}\frac{\partial}{\partial \zeta}(R_{\zeta}\frac{\partial \phi}{\partial \zeta}) = 0$$
 (3)

The total energy of the hydrogen molecular ion having a central field of +pe at each focus of the prolate spheroid molecular orbital is

$$E_{\tau} = -p^{2} \left\{ \frac{e^{2}}{8\pi\varepsilon_{o}a_{H}} (4\ln 3 - 1 - 2\ln 3) \left[1 + p \right] \frac{2\hbar \sqrt{\frac{2e^{2}}{4\pi\varepsilon_{o}[2a_{H}]^{3}}}}{\frac{m_{e}}{m_{e}c^{2}}} \left[-\frac{1}{2}\hbar \sqrt{\frac{k}{\mu}} \right] \right\}$$

$$(4)$$

$$=-p^216.13392 \ eV - p^30.118755 \ eV$$

where p is an integer, \hbar is Planck's constant bar, m_e is the mass of the electron, c is the speed of light in vacuum, μ is the reduced nuclear mass, and k is the harmonic force constant solved previously [9]. The total energy of the hydrogen molecule having a central field of +pe at each focus of the prolate spheroid molecular orbital is

$$E_{\tau} = -p^{2} \left\{ \frac{e^{2}}{8 \pi \varepsilon_{o} a_{0}} \left[\left(2\sqrt{2} - \sqrt{2} + \frac{\sqrt{2}}{2} \right) \ln \frac{\sqrt{2} + 1}{\sqrt{2} - 1} - \sqrt{2} \right] \right\} + p \sqrt{\frac{2\hbar \sqrt{\frac{e^{2}}{4 \pi \varepsilon_{o}} a_{0}^{3}}}{m_{e}}} - \frac{1}{2} \hbar \sqrt{\frac{k}{\mu}} \right\}$$
(5)

$$=-p^231.351 \ eV-p^30.326469 \ eV$$

where a_o is the Bohr radius.

The bond dissociation energy E_D of hydrogen molecular ion $H_2(1/p)^{+}$ is the difference between the total energy of the corresponding hydrogen atom H(1/p) and E_T :

$$E_D = E(H(1/p)) - E_T \tag{6}$$

where [31]

1)

$$E(H(1/p)) = -p^2 13.59844 \ eV \tag{7}$$

 E_D is given by Eqs. (6-7) and Eq. (4): $E_D = -p^2 13.59844 - E_T$

$$E_D = -p^2 13.59844 - E_T$$

$$= -p^2 13.59844 - (-p^2 16.13392 \ eV - p^3 0.118755 \ eV)$$

$$= p^2 2.535 \ eV + p^3 0.118755 \ eV$$
(8)

The bond dissociation energy E_D of hydrogen molecule $H_2(1/p)$ is the difference

between the total energy of the corresponding hydrogen atoms and E_r

$$E_D = E(2H(1/p)) - E_T \tag{9}$$

where [31]

$$E(2H(1/p)) = -p^2 27.20 \ eV \tag{10}$$

 E_D is given by Eqs. (9-10) and (5):

$$E_D = -p^2 27.20 \ eV - E_T$$

$$= -p^2 27.20 \ eV - \left(-p^2 31.351 \ eV - p^3 0.326469 \ eV\right)$$

$$= p^2 4.151 \ eV + p^3 0.326469 \ eV$$
(11)

The calculated and experimental parameters of H_2 , D_2 , H_2^+ , and D_2^+ from Ref. [9] are given in Table 1.

The vibrational and rotational energies of fractional-Rydberg-state hydrogen molecular ion $H_2(1/p)^+$ and molecular hydrogen $H_2(1/p)$ are p^2 those of H_2^+ and H_2 , respectively. Thus, the vibrational energies E_{vib} for the v=0 to v=1 transition of hydrogen-type molecular ions $H_2(1/p)^+$ are [9]

$$E_{vib} = p^2 0.271 \, eV \tag{12}$$

where p is an integer and the experimental vibrational energy for the v = 0 to v = 1 transition of H_2^+ $E_{H_2^+(v=0\to v=1)}$ is given by Karplus and. Porter [32] and NIST [33]. Similarly, the rotational energies E_{rot} for the J to J+1 transition of hydrogen-type molecular ions $H_2(1/p)^+$ are [9]

$$E_{rot} = E_{J+1} - E_J = \frac{\hbar^2}{I} [J+1] = p^2 (J+1) 0.00739 \, eV \tag{13}$$

where p is an integer, I is the moment of inertia, and the experimental rotational energy for the J=0 to J=1 transition of H_2 is given by Atkins [34].

The vibrational energies E_{vib} for the v=0 to v=1 transition of hydrogen-type molecules $H_2(1/p)$ are [9]

$$E_{vib} = p^2 0.515902 \ eV \tag{14}$$

where p is an integer and the experimental vibrational energy for the v = 0 to v = 1 transition of H_2 $E_{H_2(v=0\rightarrow v=1)}$ is given by Beutler [35] and Herzberg [36].

The harmonic oscillator potential energy function can be expanded about the internuclear distance and expressed as a Maclaurin series corresponding to a Morse potential after Karplus and Porter (K&P) [32] and after Eq. (96) of Ref. [9]. Treating the Maclaurin series terms as anharmonic perturbation terms of the harmonic states, the energy corrections can be found by perturbation methods. The energy $\tilde{v}_{\nu+1}$ of state $\nu = \nu' + 1$ is

$$\tilde{\nu}_{u+1} = (v'+1)\omega_0 - v'(v'+1)\omega_0 x_0, \quad v' = 0,1,2,3...$$
 (15)

where

$$\omega_0 x_0 = \frac{hc \,\omega_0^2}{4D_0} \tag{16}$$

From Eqs. (11), (14), and (16)

$$\omega_0 x_0 = \frac{hc \,\omega_0^2}{4D_0} = \frac{100hc \left(8.06573 \,X10^3 \,\frac{cm^{-1}}{eV} \,p^2 \,0.5159 \,eV \right)^2}{4e \left(p^2 \,4.151 \,eV + p^3 \,0.326469 \,eV \right)} \,cm^{-1} \tag{17}$$

Using Eqs. (14-17) with p = 1 and p = 4, gives

$$\tilde{\nu}_{\nu+1} = (\nu'+1)4161 \ cm^{-1} - \nu' (\nu'+1)119.9 \ cm^{-1}$$

$$E_{\nu ib \ \nu'+1} = (\nu'+1)0.5159 \ eV - \nu' (\nu'+1)0.01486 \ eV, \qquad \nu' = 0,1,2,3...$$
(18)

and

$$\tilde{\nu}_{\upsilon+1} = (\upsilon'+1)66,578 \ cm^{-1} - \upsilon \ (\upsilon'+1)1574 \ cm^{-1}$$

$$E_{\upsilon b \ \upsilon+1} = (\upsilon'+1)8.254 \ eV - \upsilon' \ (\upsilon'+1)0.1951 \ eV$$
(19)

respectively, where the calculated $\omega_0 x_0 = 119.9 \text{ cm}^{-1}$ for H_2 is in agreement with the literature values of 117.91 cm⁻¹ from K&P [32] and 121.34 cm⁻¹ from Lide [37].

Similarly to $H_2(1/p)^+$, the rotational energies E_{rot} for the for the J to J+1 transition of hydrogen-type molecules $H_2(1/p)$ are [9]

$$E_{rot} = E_{J+1} - E_J = \frac{\hbar^2}{I} [J+1] = p^2 (J+1)0.01509 \ eV$$
 (20)

where p is an integer, I is the moment of inertia, and the experimental rotational energy for the J = 0 to J = 1 transition of H_2 is given by Atkins [34].

The p^2 dependence of the rotational energies results from an inverse p dependence of the internuclear distance and the corresponding impact on I. The predicted internuclear distances 2c' for $H_2(1/p)^+$ and $H_2(1/p)$ are

$$2c' = \frac{2a_o}{p} \tag{21}$$

and

$$\frac{a_o\sqrt{2}}{p} 2c' = \frac{a_o\sqrt{2}}{p} \tag{22}$$

respectively.

B. Experiments to Test the Theoretical Predictions

The reaction Ar^+ to Ar^{2+} has a net enthalpy of reaction of 27.63 eV; thus, it may serve as a catalyst to form H(1/2). The product of the catalysis reaction H(1/2) may further serve as both a catalyst and a reactant to form H(1/4) [2-3]. Also, the second ionization energy of helium is $54.4 \ eV$; thus, the ionization reaction of He^+ to He^{2+} has a net enthalpy of reaction of $54.4 \ eV$ which is equivalent to $2 \cdot 27.2 \ eV$. The product of the catalysis reaction H(1/3) may further serve as both a catalyst and a reactant to form H(1/4) and H(1/2) [2-3].

Since $H_2(1/2)^+$ is a resonant state of $H_2(1/4)^+$, the reaction designated $H(1/4) + H^+ \to H_2(1/4)^+ \tag{23}$

wherein H(1/4) reacts with a proton to form $H_2(1/4)^+$ is possible with strong emission through vibronic coupling with the resonant state $H_2(1/2)^+$. The frequencies of resonant states of a time harmonic oscillator are an integer of the fundamental frequency corresponding to integer energy separation. The bond energy may be emitted with the energies of vibrational transitions in the transition state that superimpose to give emission to longer wavelengths of that corresponding to the bond energy.

As given previously [9], during bond formation, the electrons undergo a reentrant oscillatory orbit with vibration of the protons. The corresponding energy \overline{E}_{osc} is the difference between the Doppler \overline{E}_D and average vibrational kinetic energies \overline{E}_{Kvib} . The latter term from Eq. (4) is given by $\frac{1}{2}\hbar\sqrt{\frac{k}{\mu}}$. Transitions are possible involving the formation of $H_2(1/4)^+$ in an

excited vibrational state of the transition state with the emission of the bond energy minus this additional vibrational energy where the vibrational energy of the transition state given by Eq. (108) of Ref. [9] is

$$E_{vib} = \hbar \omega = \hbar p^2 4.44865 \times 10^{14} \text{ rad/s} = p^2 0.2928 \text{ eV}$$
 (24)

Thus, with the resonant state of p=2, an energy of an integer times the vibrational energy of $H_2(1/2)^+$ plus \overline{E}_{Kvib} goes to vibrational excitation. The energies E_{D+vib} of this series due to vibration in the transition state are given by

transition state are given by
$$E_{D+vib} = E_D \left(H_2 (1/4)^+ \right) - \left(v^* + \frac{1}{2} \right) 2^2 E_{vib H_2^+}, \quad v^* = 0, 1, 2, 3...$$

$$= 48.16 - \left(v^* + \frac{1}{2} \right) 1.172 \ eV$$
(25)

where $E_D(H_2(1/4)^+)$ is the bond energy of $H_2(1/4)^+$ given by Eq. (8) and $E_{vibH_2^-}$ is the vibrational energy of H_2^+ in the transition state given by Eq. (24). In Eq. (25), v^* refers to vibrational energies of the transition state which must have equal energy separation as a requirement for resonant emission [9]. Thus, anharmonicity is not predicted. The series is predicted to end at 25.74 nm corresponding to the predicted $H_2(1/4)^+$ bond energy of 48.16 eV given by Eq. (8).

It was described previously that the reaction of H(1/p) with a proton may also involve an excited electronic state and a series of corresponding vibrational and rotational state emission lines [5]. In the reaction designated

$$H(1/2) + H^{+} \rightarrow H_{2}^{*}[n = 1/4; n^{*} = 2]^{+}$$
 (26)

H(1/2) reacts with a proton to form an excited electronic state of the molecular ion $H_2(1/4)^+$ wherein the central field in elliptic coordinates is one half that of ground state (nonradiative

state) of $H_2(1/4)^+$. This state is analogous to the n=2 state of atomic hydrogen and is designated as $H_2^+[n=1/4;n^*=2]^+$, except that electronic relaxation may involve a radiationless process with a radiative component involving the oscillating and rotating nuclei which transition to the v=0 state of $H_2(1/4)^+$. The nonradiative energy transfer corresponding to $H(1/2) \rightarrow H(1/4)$ may occur from highest vibrational state (bond-continuum state) of $H_2(1/2)^+$. The absence of anharmonicity favors the proposed mechanism given by Eq. (25) over one given previously [5] corresponding to Eq. (26).

The present paper tests theoretical predictions [1-5, 8-13] that atomic and molecular hydrogen form stable states of lower energy than traditionally thought possible. Substantial spectroscopic and physical differences are anticipated. For example, novel EUV atomic, molecular ion, and molecular spectral emission lines from transitions corresponding to energy levels given by Eqs. (2a) and (2c), Eq. (4), and Eq. (5), respectively, are predicted. The atomic lines have been shown previously [1-4, 26] as well as a series of unique EUV lines assigned to $H_2(1/2)$ [4]. To test further predictions, EUV spectroscopy was performed to search for emission that was characteristic of and identified $H_2(1/4)^+$ and $H_2(1/4)$. Low pressure plasmas are more highly ionized. Thus, we further investigated the emission of the $H_2(1/4)^+$ vibrational series given by Eq. (25) from microwave discharges of helium-hydrogen and argon-hydrogen mixtures. The resolution of the spectra was improved compared to those recorded previously [5] by reducing each of the slits 1.5 to 7.5 times. Also, exact, closed-form solutions of hydrogen molecular ions and molecules are available for testing [9].

The rotational energies provide a very precise measure of I and the internuclear distance using well established theory [32]. Neutral molecular emission was anticipated for high pressure argon-hydrogen plasmas excited by a 15 keV electron beam. Rotational lines for $H_2(1/4)$ were anticipated and sought in the 150-250 nm region. The spectral lines were compared to those predicted by Eqs. (19-20) corresponding to the internuclear distance of 1/4 that of H_2 given by Eq. (22). The predicted energies for the $v=1 \rightarrow v=0$ vibration-rotational series of $H_2(1/4)$ (Eqs. (19-20)) are

$$E_{vib-rol} = p^{2} E_{vib H_{2}(\nu=0 \to \nu=1)} \pm p^{2} (J+1) E_{rol H_{2}}$$

$$= 4^{2} E_{vib H_{2}(\nu=0 \to \nu=1)} \pm 4^{2} (J+1) E_{rol H_{2}} , \quad J = 0,1,2,3...$$

$$= 8.254432 \ eV \pm (J+1)0.24144 \ eV$$
(27)

for p = 4.

The product $H_2(1/p)$ gas was isolated by liquefaction at liquid nitrogen temperature. The boiling point of the novel molecular hydrogen product is predicted to be different from that of H_2 . The ℓ quantum number of $H_2(1/p)$ may be different from zero [8-9] which would give rise to a dipole moment with a corresponding significant increase in the liquefaction temperature

relative to H_2 with no dipole moment. Furthermore, as shown previously [5, 8-9], the parameter of $H_2(1/p)$ corresponding to the radius in elliptic coordinates is 1/p times that of H_2 with a corresponding charge density of a factor p^2 times greater than that of H_2 . Thus, $H_2(1/p)$ gas may condense at a higher temperature than H_2 due to greater corresponding van der Waals effects as given by the van der Waals equation:

$$P = \frac{RT}{\overline{V} - b} - \frac{a}{\overline{V}^2} \tag{28}$$

In Eq. (28), P is pressure of the gas at a given temperature T and volume per mole \overline{V} , and a and b are constants that depend on the particular gas. The term $\frac{a}{\overline{V}^2}$ is meant to correct for the effect of attractive intramolecular forces that lower the pressure. This effect is predicted to be larger for $H_2(1/p)$ compared to H_2 . In addition, the nonzero volume of the molecules themselves decreases the volume available for them to move; so, some volume b is subtracted from \overline{V} . Again, the smaller volume of $H_2(1/p)$ compared to H_2 favors a lower pressure at a given temperature, or equivalently, favors liquefaction at a higher temperature.

Helium-hydrogen (90/10%) plasma gases were flowed through a high-vacuum (10^{-6} Torr) capable, liquid nitrogen (LN) cryotrap, and the condensed gas was characterized by ^{1}H nuclear magnetic resonance (NMR) of the LN-condensable gas dissolved in $CDCl_{3}$. Other sources of hydrogen such as hydrocarbons were eliminated by mass spectroscopy (MS) and Fourier transform infrared spectroscopy (FTIR). The ^{1}H NMR resonance of $H_{2}(1/p)$ is predicted to be upfield from that of H_{2} due to the fractional radius in elliptic coordinates [8-9] wherein the electrons are significantly closer to the nuclei. The predicted shift $\frac{\Delta B_{T}}{B}$ for $H_{2}(1/p)$ derived previously [8-9] is given by the sum of that of H_{2} and a relativistic term that depends on p > 1:

$$\frac{\Delta B_T}{B} = -\mu_0 \left(4 - \sqrt{2} \ln \frac{\sqrt{2} + 1}{\sqrt{2} - 1} \right) \frac{e^2}{36a_0 m_a} \left(1 + \pi \alpha p \right)$$
 (29)

$$\frac{\Delta B_T}{B} = -(28.01 + 0.64 \, p)ppm \tag{30}$$

where p = 0 for H_2 since there is no relativistic effect and p = integer > 1 for $H_2(1/p)$ where p = integer > 1.

In addition to liquefaction at liquid nitrogen temperature, $H_2(1/p)$ gas was also isolated by decomposition of compounds found to contain the corresponding hydride ions $H^-(1/p)$. The total shift $\frac{\Delta B_T}{B}$ was calculated previously [8, 20] for the hydride ions $H^-(1/p)$ having a fractional principal quantum number. The shift was given by the sum of that of ordinary hydride ion H^- and a component due to a relativistic effect:

$$\frac{\Delta B_T}{B} = -\mu_0 \frac{e^2}{12 m_e a_0 \left(1 + \sqrt{s(s+1)}\right)} \left(1 + \alpha 2 \pi p\right) = -(29.9 + 1.37 p) ppm$$
 (31)

where p = 0 for H^- since there is no relativistic effect and p = integer > 1 for $H^-(1/p)$ where p = integer > 1. The experimental absolute resonance shift of tetramethylsilane (TMS) is -31.5 ppm relative to the proton's gyromagnetic frequency [38-39]. The results of ¹H MAS NMR spectroscopy were given previously [20, 28-30] on control and novel hydrides synthesized using atomic potassium as a hydrogen catalyst wherein the triple ionization reaction of K to K^{3+} , has a net enthalpy of reaction of 81.7766 eV, which is equivalent to $3 \cdot 27.2 \text{ eV}$. The KH experimental shift of +1.3 ppm relative to TMS corresponding to absolute resonance shift of -30.2 ppm matched very well the predicted shift of H^- of -30 ppm given by Eq. (31). The ¹H MAS NMR spectrum of novel compound KH^+ Cl relative to external tetramethylsilane (TMS) showed a large distinct upfield resonance at -4.4 ppm corresponding to an absolute resonance shift of -35.9 ppm that matched the theoretical prediction of p = 4. A novel peak of k + 1 at -1.5 ppm relative to TMS corresponding to an absolute resonance shift of -33.0 ppm matched the theoretical prediction of p = 4. The predicted catalyst reactions, position of the upfield-shifted NMR peaks, and spectroscopic data for $H^-(1/2)$ and $H^-(1/4)$ were found to be in agreement [9, 20].

The decomposition reaction of
$$H^{-}(1/p)$$
 is
$$2M^{+}H^{-}(1/p) \xrightarrow{\Delta} H_{2}(1/p) + 2M$$
(32)

where M^+ is a metal ion. NMR peaks of $H_2(1/p)$ given by Eqs. (29-30) provide a direct test of whether compounds such as KH * I contain hydride ions in the same fractional quantum state p. Furthermore, the observation of a series of singlet peaks upfield of H_2 with a predicted integer spacing of 0.64 ppm provides a powerful means to confirm the existence of $H_2(1/p)$.

The exothermic helium plasma catalysis of atomic hydrogen was shown previously [14-15] by the observation of an average hydrogen atom temperature of $180-210 \, eV$ for helium-hydrogen mixed plasmas versus $\approx 3 \, eV$ for hydrogen alone. Since the electronic transitions are very energetic power balances of helium-hydrogen plasmas compared to control krypton plasmas were measured using water bath calorimetry to determine whether this reaction has sufficient kinetics to merit its consideration as a practical power source.

II. Experimental

To investigate the vibrational series of $H_2(1/4)^+$, EUV spectra (20-65 nm) were recorded on light emitted from microwave discharge plasmas of helium, argon, krypton, or xenon or a mixture of 10% hydrogen with each noble gas. Each ultrapure test gas or mixture was flowed

through a half inch diameter quartz tube at 100 mTorr maintained with a total gas flow rate of 10 sccm. The tube was fitted with an Opthos coaxial microwave cavity (Evenson cavity). The microwave generator was an Opthos model MPG-4M generator (Frequency: 2450 MHz). The input power to the plasma was set at 40 W.

٠,٠

The spectrometer was a McPherson 4° grazing incidence EUV spectrometer (Model 248/310G) equipped with a grating having 600 G/mm with a radius of curvature of $\approx 1 m$ that covered the region 5-65 nm. The angle of incidence was 87°. The wavelength resolution was about 0.1 nm (FWHM) with an entrance and exit slit width of 40 μm . A CEM was used to detect the EUV light. The increment was 0.01 nm and the dwell time was 1 s.

Vibration-rotational emission of $H_2(1/4)$ was investigated using an electron gun provided by Rutgers University and described previously [40-41] to initiate argon plasmas with 1% hydrogen and oxygen or nitrogen in the pressure range of 450-1000 Torr. Krypton replaced argon in the controls. The electrons were accelerated with a high voltage of 12.5 keV at a beam current of 10 μ A. The electron gun was sealed with a thin (300 nm thickness) SiN_x foil that served as a 1 mm² electron window to the cell at high gas pressure (760 torr). The beam energy was deposited by hitting the target gases, and the light emitted by beam excitation exited the cell thorough a MgF₂ window mounted at the entrance of a normal incidence McPherson 0.2 meter monochromator (Model 302) equipped with a 1200 lines/mm holographic grating with a platinum coating. The wavelength region covered by the monochromator was 5-560 nm. The EUV spectrum was recorded with a photomultiplier tube (PMT). The wavelength resolution was about $0.8 \, nm$ (FWHM) with an entrance and exit slit width of $200 \, \mu m$. The increment was 0.1 nm and the dwell time was 1 s. The PMT (Model R8486, Hamamatsu) used has a spectral response in the range of 115-320 nm with a peak efficiency at about 225 nm. The emission was essentially flat for $200 < \lambda > 275 \, nm$, but a notch in the response existed in the short wavelength range with a minimum at 150 nm. Peak assignments were based on an external calibration against standard line emissions.

Condensable gas from helium-hydrogen (90/10%) microwave plasmas maintained in the Evenson cavity was collected in a high-vacuum (10⁻⁶ Torr) capable, LN cryotrap shown in Figure 1 as described previously [27]. After each plasma run the cryotrap was pumped down to 10⁻⁵ Torr to remove any non-condensable gases in the system. The pressure was recorded as a function of time as the cryotrap was warmed to room temperature. Typically, about 3 Torr of condensed gas was collected in a 2 hr plasma run. Controls were hydrogen and helium alone.

The mass spectra (m/e = 1 to m/e = 200) of ultrahigh purity hydrogen (Praxair) control samples and samples of the condensable gas from the helium-hydrogen microwave plasmas were recorded with a residual gas analyzer.

Gases from a 700 mTorr He/H₂ (90/10%) Evenson microwave plasma were flowed

through a long capillary tube which was maintained in the temperature range ~12-17 K by a cryo-cooler. Residual gas was pumped from the capillary, condensable gas was collected over a period of several hours, and the system was evacuated to 10⁻⁵ Torr to remove any non-condensable gases in the system. Controls were hydrogen and helium alone. Two capillary valves were closed to trap any vaporizing gas as the cryo-cooler was stopped, and the tube was warmed to room temperature. Typically about 100 mTorr of gas was collected over a 24 to 48 hour period and then analyzed by mass spectroscopy and compared with the results for a control sample collected in the same way, except without plasma.

. .

The system comprised welded stainless steel tubing with metal gasket and rubber o-ring connections as shown in Figure 2. Premixed He/H_2 (90/10%) was flowed from a supply bottle through a metering valve and a LN trap just upstream of the plasma tube. A second LN trap downstream of the plasma tube was used to remove any water vapor generated by the plasma. The process gas pressure was monitored by a Baratron absolute pressure gauge upstream of the cryo-head. The cryo-cooler comprised a compressor (CTI Model SC) and cryo-head (CTI Cryogenics Model 22). The principle component of the cryo-head was an evacuated cylindrical chamber of approximately one liter volume through which the cryogenic refrigerant was circulated in a closed system. A stainless steel cold stage extended from the base of the chamber on the chamber axis. A fabricated cylindrical copper spindle was attached to the existing cold stage by screws. Thermal contact resistance between the spindle and cold stage was minimized by an intervening layer of conducting grease. Approximately 1.7 m of copper capillary tubing, 1.56 mm OD and 0.88 mm ID, was wound onto a spiral groove with 5.5 grooves per cm pitch machined onto the spindle. The capillary tube was fused to the spindle along its span with tin/lead solder. A cryogenic silicon diode temperature sensor was also attached to the spindle just beneath the capillary winding. The sensor output was monitored with a readout (TRI Research Cryo-Controller Model T-2000). The sensor accuracy was better than ± 0.1 K in the range 10-300 K.

The system was connected to either a Dycor Model DM200MS or Model D200MP mass spectrometer through a sampling tube. A background scan (m/e = 1 to m/e = 200) was acquired for reference before introducing the collected gas to the mass spectrometer. Then, the valve just downstream of the cryo-head was opened, allowing gas to flow into the sample tube and spectrometer. Several scans were taken over a period of about 10 minutes while gas was slowly drawn out of the capillary tube into the spectrometer.

Sealed ¹H NMR samples were prepared by collecting the condensed gas from the cryotrap in CDCl₃ solvent (99.99% Cambridge isotopes) in an NMR tube (5 mm OD, 23 cm length, Wilmad) maintained at LN-temperature which was then sealed as described previously [27]. Control NMR samples comprised ultrahigh purity hydrogen (Praxair) and the helium-

hydrogen (90/10%) mixture with *CDCl*₃ solvent. The NMR spectra were recorded with a 300 MHz Bruker NMR spectrometer that was deuterium locked. The chemical shifts were referenced to the frequency of tetramethylsilane (TMS) at 0.00 ppm.

KH*1 that was prepared under long duration (two weeks) synthesis according to methods given previously [28-30], and one gram samples were placed in a thermal decomposition reactor under an argon atmosphere. The reactor comprised a 1/4" OD by 3" long quartz tube that was sealed at one end and connected at the open end with Swagelock™ fittings to a T. One end of the T was connected to the NMR tube containing CDCl₃ solvent, and the other end was attached to a turbo pump. The apparatus was evacuated to less than 1 milliTorr with the CDCl₃ maintained at LN temperature. The sample was heated to 200 °C under vacuum. A valve to the pump was closed, and the sample was heated in the evacuated quartz chamber containing the sample to above 600 °C until the sample melted. Gas released from the sample was collected in the CDCl₃ solvent, the NMR tube was sealed and warmed to room temperature, and the NMR spectrum was recorded. Using identical samples, the NMR-tube end of the collection apparatus was connected directly to the sampling port of a quadrupole mass spectrometer to test for hydrocarbon contamination. FTIR was also performed on the released gas for this purpose.

An NMR sample from KH*I provided by BlackLight Power, Inc. was also prepared and analyzed at the Naval Air Warfare Center Weapons Division, Naval Air Warfare Center, China Lake, CA under the same procedure except that the $CDCl_3$ solvent was maintained at ice temperature during hydrogen gas collection, and the NMR spectrum was recorded with a 400 MHz instrument at China Lake. Control NMR samples of ultrapure hydrogen dissolved in $CDCl_3$ solvent were also prepared, and NMR spectra were obtained under conditions matching those of the KH*I-derived samples.

The excess power was measured by water bath calorimetry on helium-hydrogen (95/5%) plasmas maintained in a microwave discharge cell compared to control plasmas with the same input power as described previously [26]. The system is shown in Figure 3. The water bath was calibrated by a high precision heater and power supply. A high precision linear response thermistor probe (Omega OL-703) recorded the temperature of the 45 L water bath as a function of time for the stirrer alone to establish the baseline. The heat capacity was determined for several input powers, 30, 40, and 50 W \pm 0.01 W, and was found to be independent of input power over this power range within \pm 0.05%. The temperature rise of the reservoir as a function of time gave a slope in °C/s. This slope was baseline corrected for the negligible stirrer power and loss to ambient. The constant known input power (J/s), was divided by this slope to give the heat capacity in J/°C. Then, in general, the total power output from the cell to the reservoir was determined by multiplying the heat capacity by the rate of temperature rise (°C/s) to give J/s.

Since the cell and water bath system were adiabatic, the general form of the power balance equation with the possibility of excess power is:

$$P_{in} + P_{ex} - P_{out} = 0 ag{33}$$

where P_{in} is the microwave input power, P_{ex} is the excess power generated from the hydrogen catalysis reaction, and P_{out} is the thermal power loss from the cell to the water bath. Since the cell was surrounded by water that was contained in an insulated reservoir with negligible thermal losses, the temperature response of the thermistor T as a function of time t was determined to be

$$\dot{T}(t) = (1.940 \times 10^5 \text{ J/°C})^{-1} \times P_{out}$$
 (34)

where $1.940 \times 10^5 J/^{\circ}C$ is the heat capacity for the least square curve fit of the response to power input for the control experiments ($P_{ex} = 0$). The slope was recorded for about 2 hours after the cell had reached a thermal steady state, to achieve an accuracy of $\pm 1\%$.

III. Results and Discussion

A. EUV spectroscopy of Helium-Hydrogen and Argon-Hydrogen Plasmas

a. Detection of Fractional Rydberg State Hydrogen Molecular Ion $H_1(1/4)^{\dagger}$

In the case of the EUV spectra of helium, krypton, xenon, krypton-hydrogen (90/10%), or xenon-hydrogen (90/10%), no peaks were observed below 65 nm, and no spurious peaks or artifacts due to the grating or the spectrometer were observed. No changes in the emission spectra were observed by the addition of hydrogen to noncatalysts krypton or xenon. Only known atom and ion peaks were observed in the EUV spectrum of the helium and argon microwave discharge emission.

The EUV spectra (20-65 nm) of the microwave plasmas of xenon and 10% hydrogen mixed with helium, krypton, and xenon are shown in Figure 4. No emission was observed from the noncatalyst controls, krypton and xenon. A characteristic vibrational series was observed for helium-hydrogen (90/10%), but at higher energies than any known molecule by about an order of magnitude. The series was not observed with helium alone as shown in Figure 5. The energies of the peaks observed in Figures 4 and 5 are plotted in Figure 6 as a function of peak number or integer v^* . The slope of the linear curve fit in Figure 6 is 1.18 eV, and the intercept is 47.6 eV which matches the predicted series given by Eq. (25) to within the spectrometer resolution of 1%. This energy separation matches the vibrational energy of the resonant state $H_2(1/2)^+$, and the series terminates at about 25.7 nm corresponding to the predicted bond energy of $H_2(1/4)^+$ of 48.16 eV given by Eq. (8). The absence of anharmonicity identifies the mechanism given by Eq. (25) over that given by Eq. (26). Thus, emission in this region is due to the reaction

 $H(1/4) + H^+ \rightarrow H_2(1/4)^+$ with vibronic coupling with the resonant state $H_2(1/2)^+$ within the transition state. The predicted emission at $E_{D+vib} = E_D \left(H_2(1/4)^+\right) - \left(\upsilon^* + \frac{1}{2}\right)2^2 E_{vib\,H_1^*}$ was observed for $\upsilon^* = 0,1,2,3...24$. All other peaks in the spectra were assigned to He I and He II.

The EUV spectra (20-65 nm) of microwave plasmas of argon-hydrogen (90/10%) compared with argon alone are shown in Figure 7. The vibrational series of peaks with an energy spacing of 1.18 eV was observed from the argon-hydrogen plasma having Ar^{+} catalyst with hydrogen. In contrast, the series was not observed without hydrogen. The peaks matched Eq. (25) for $v^* = 0,1,2,3...24$.

b. Detection of Fractional Rydberg State Molecular Hydrogen H, (1/4)

The observation of emission due to the reaction $H(1/4) + H^+ \rightarrow H_2(1/4)^+$ at low pressure (< 1 Torr) shown in Figures 4 and 5 indicates that H(1/4) formed in the argonhydrogen plasma. Molecular formation was anticipated under high-pressure conditions (~760 Torr). Thus, EUV spectroscopy of argon-hydrogen plasmas was performed to search for $H_2(1/4)$ from H(1/4) formed by Ar^+ as a catalyst. Rather than using the 4° grazing incidence EUV spectrometer, the normal incidence spectrometer was used at high pressure which required a window and a electron beam to maintain a plasma. Since the 15 keV beam rapidly transfers energy to the target gas and produces a large population of species with energies of a few 10's of eVs of kinetic energy, it was anticipated that the beam could directly or indirectly collisionally excite vibration-rotational states of $H_2(1/4)$. The corresponding emission provides a direct measure of the internuclear distance; thus, this method provides the possibility of direct confirmation of $H_2(1/4)$.

The atmospheric-pressure argon plasma formed with the 15 keV electron beam contains a high population of excimers such as Ar_2 * [40-41]. Ar_2 * has an excited state energy of about 9-10 eV; thus, the ionization reaction

$$Ar_{2}^{*} + O^{\dagger} \rightarrow Ar + Ar^{\dagger} + O \tag{35}$$

is energetically favorable wherein the first ionization energies of Ar and O are 15.75962 and 13.61806 eV, respectively. Ar^+ serves as a catalyst when H is present. Thus, spectra were recorded on argon-hydrogen-oxygen plasmas maintained with a 15 keV electron beam. The 100-350 nm spectrum of a 783 Torr plasma of argon containing about 1% hydrogen and oxygen is shown in Figure 8. Lyman α was observed at 121.6 nm with an adjoining H_2 band, the third continuum of Ar was observed at 210 nm [41], and the OH(A-X) bands were observed at 282.7 and 308.6 nm [24, 42-43]. A series of sharp, evenly-spaced lines was observed in the region 145-185 nm. The only possibilities for the source of the sharp peaks are rotational, atomic, or ion transitions. None of the strong O I and O II lines match any of the lines [33]. No

combination of O species matches the evenly spaced lines. The series was not observed with argon alone, and only Ar VII and Ar VIII are possible in this region which is not possible at this pressure. Furthermore, no argon species match the observed lines [33].

The series matched the P branch of $H_2(1/4)$ for the vibrational transition $v=1 \rightarrow v=0$. P(1), P(2), P(3), P(4), P(5), and P(6) were observed. The sharp peak at 146.84 nm may be the first member of the R branch, R(1). The PMT has a response-notch in the region of the R branch, but the R-branch lines may correspond to forbidden transitions. Selection rules for $H_2(1/p)$ may be $\Delta v = -1$ $\Delta J = +1$ in order for a net state change with vibration-rotation coupling. Alternatively, the emission could be suppressed by the argon second continuum, or the vibrational energy may favor partial internal conversion rather than emission. Similarly, as shown in Sec. IIIAa, the $H_2(1/4)^+$ series was only observed for wavelengths longer than the bond energy corresponding to the result that only the P branch of $H_2(1/4)$ was allowed.

The plot of the energies of the peaks shown in Figure 8 is shown in Figure 9. The slope of the linear curve fit is 0.245 eV with an intercept of 8.224 eV which matches Eq. (27) very well for p = 4. The series matches the predicted $v = 1 \rightarrow v = 0$ vibrational energy of $H_2(1/4)$ of 8.2544 eV (Eq. (14)) and its predicted rotational energy spacing of 0.241 eV (Eq. (20)) with $\Delta J = +1$; J = 0,1,2,3,4,5.

The vibration-rotational series was observed only when oxygen was also present with hydrogen. For oxygen, there are several chemical reactions that fulfill the catalyst criterion. The bond energy of the oxygen molecule is 5.165 eV, and the first, second, and third ionization energies of an oxygen atom are 13.61806 eV, 35.11730 eV, and 54.9355 eV, respectively [31]. The reactions $O_2 \rightarrow O + O^{2+}$, $O_2 \rightarrow O + O^{3+}$, and $2O \rightarrow 2O^{+}$ provide a net enthalpy of about 2, 4, and 1 times E_h , respectively. It was previously reported that H lines were selectively broadened and that both the Lyman and the Balmer α lines were observed to be inverted in certain plasmas with oxygen catalyst [24-25]. However, oxygen may serve a role other than as a catalyst to give rise to the vibration-rotational series. Emission of the $H_2(1/4)$ vibration-rotational series may occur via electron-collisional excitation of O_2 followed by vibration-rotational activation of $H_2(1/4)$ through a collisional energy exchange with the excited O_2 :

$$O_2^* + H_2(1/4) \rightarrow O_2 + H_2(1/4)^*$$
 (36)

where * denotes an energetic state. This mechanism is favored at the high operating pressure. Furthermore, the role of argon as the source of the catalyst was shown by the absence of the vibration-rotational series when krypton replaced argon. Thus, the activation role of a molecule is implicated.

It was anticipated that if selection rules or kinetics require that the $H_2(1/4)$ be vibrationrotationally excited by a collisional energy exchange with a molecule, then nitrogen may be effective as well. It was also anticipated that lower pressure could result in higher kinetic energies and result in the excitation of $H_2(1/4)$ to higher vibration-rotational energies. The 100-350 nm spectrum of a 456 Torr plasma of argon containing about 1% hydrogen and nitrogen is shown in Figure 10. Lyman α was observed at 121.6 nm, the third continuum of Ar was observed at 190 nm [41], and background molecular emission was observed including $N_2 C^3 \Pi_u - B^3 \Pi_g$ emission in the 270-350 region [44-46]. The series of sharp, evenly-spaced lines observed for trace oxygen addition was observed for nitrogen but in the region 200-275 nm. Again, the only possibilities for the source of the sharp peaks are rotational, atomic, or ion transitions. None of the strong N I and N II lines match any of the lines [33]. No combination of N I and N II lines matches the evenly spaced lines. Rather than nitrogen line emission, molecular emission was observed as previously recorded on air-plasma discharges [44-46].

The series matched the P branch of $H_2(1/4)$ for the vibrational transition $v = 5 \rightarrow v = 4$. P(1), P(2), P(3), P(4), P(5), P(6), and P(7) were observed. In this case, the R-branch lines also appeared to correspond to forbidden transitions. Alternatively, the emission could be suppressed by the argon third continuum. The plot of the energies of the peaks shown in Figure 10 is shown in Figure 11. The slope of the linear curve fit is 0.245 eV with an intercept at 6.25 eV which matches Eqs. (19) and (27) very well for p = 4. The series matched the predicted $v = 5 \rightarrow v = 4$ vibrational energy of $H_2(1/4)$ of 6.30 eV (Eq. (19)) and its predicted rotational energy spacing of 0.241 eV (Eq. (20)) with $\Delta J = +1$; J = 0,1,2,3,4,5,6. Using Eqs. (20) and (22) with the measured rotational energy spacing of 0.24 eV establishes an internuclear distance of 1/4 that of the ordinary hydrogen species for $H_2(1/4)$. This technique which is the best measure of the bond distance of any diatomic molecule identifies and unequivocally confirms $H_2(1/4)$.

A possible confirmation of the novelty of the lines identified in this study or similar lines has been published previously. The comparison of the third continuum of argon gas as recorded by Ulrich, Wieser, and Murnick [41] with a very pure gas (upper spectrum) and a spectrum in which the gas was slightly contaminated by oxygen as evidenced by the second order of the 130 nm resonance lines at 160 nm is shown in Figure 12. A series of narrow, evenly-spaced lines that appear similar to those in Figures 8 and 10 were observed that could not be assigned by Ulrich et al. to known species. The series was not observed in krypton and xenon plasmas. The determination of the presence of hydrogen in the argon plasmas is warranted in future studies.

B. Isolation and Characterization of $H_2(1/p)$

a. Cryotrap Pressure

Helium-hydrogen (90/10%) gas was flowed through the microwave tube and the cryosystem for 2 hours with the trap cooled to LN temperature. No change in pressure over time was observed when the dewar was removed, and the system was warmed to room temperature as

shown in Figure 13. The experiment was repeated under the same conditions but with a plasma maintained with 60 W forward microwave power and 10 W reflected. In contrast to the control case, a liquid-nitrogen-condensable gas was generated in the helium-hydrogen plasma reaction since the pressure due to the reaction product rose from 10⁻⁵ Torr to 3 Torr as the cryotrap warmed to room temperature.

b. Mass Spectroscopy

The mass spectrum for the gases collected in the cryotrap from the He/H_2 (90/10%) plasma over the range m/e=1 to m/e=200 showed that the LN-condensable gas was highly pure hydrogen. The mass spectrum for the (m/e=1 to m/e=50) region is shown in Figure 14a. The mass spectrum (m/e=1 to m/e=200) for the gases collected in the cryo-cooler from the He/H_2 (90/10%) plasma only showed peaks in the (m/e=1 to m/e=50) region. The m/e=2 peak shown in Figure 14b was 40-50 times more intense than the m/e=28 (nitrogen), m/e=32 (oxygen), and m/e=40 (argon) peaks that were assigned to very trace residual air contamination. Whereas, without the plasma, the mass m/e=2 peak was present in only trace concentration ($\sim 10^{-10}$ Torr) compared with the air contaminant gases that were also present in low abundance ($\sim 10^{-9}$ Torr). Von Engel [47] gives the efficiency of production of various common ions at 70 eV and shows that the cross section for the formation of H_2^+ is 10% of that of air contaminants at the same partial pressure. Thus, hydrogen was ~ 500 times more abundant in the collected gas than air contaminants which may have originated through back-streaming in the mass spectrometer.

The phase diagram of helium and hydrogen is shown in Figure 15 that was plotted from data given by Lide [48] and extended to lower pressures and temperatures using the Clausius-Clapeyron equation [49]. It is not possible to condense ordinary hydrogen below ~50 Torr at 12-17 K as shown by its phase diagram. The condensation of a m/e = 2 gas in the temperature range of 12-17 K at 700 mTorr that was not removed at 10^{-5} Torr indicates that a novel hydrogen gas formed in the plasma reaction between hydrogen and helium. The results are even more dramatic in the case of the condensation of a m/e = 2 gas in the temperature range of 77 K using the LN cryotrap.

c. ¹H NMR

The 1H NMR on $CDCl_3$ showed only a singlet solvent $(CHCl_3)$ peak at 7.26 ppm relative to tetramethylsilane (TMS) with small ^{13}C side bands. The 1H NMR on ultrahigh purity hydrogen dissolved in $CDCl_3$ relative to tetramethylsilane (TMS) showed only singlet peaks at 7.26, 4.63, and 1.57 ppm corresponding to $CHCl_3$, H_2 , and H_2O , respectively. The chemical shifts of the $CHCl_3$ and H_2O peaks matched the literature values of 1.56 and 7.26 ppm,

respectively [50]. The error in the observed peaks was determined to be ± 0.01 ppm. The ^{1}H NMR spectroscopic results of the control prepared from the reagent helium-hydrogen mixture was the same as that of the high purity hydrogen control.

 H_2 has been characterized by gas phase ¹H NMR. The experimental absolute resonance shift of gas-phase TMS relative to the proton's gyromagnetic frequency is -28.5 ppm [51]. H_2 was observed at 0.48 ppm compared to gas phase TMS set at 0.00 ppm [52]. Thus, the corresponding absolute H_2 gas-phase resonance shift of -28.0 ppm (-28.5 + 0.48) ppm was in excellent agreement with the predicted absolute gas-phase shift of -28.01 ppm given by Eq. (30).

The absolute H_2 gas-phase shift can be used to determine the solvent shift for H_2 dissolved in $CDCl_3$. The correction for the solvent shift can then be applied to other peaks to determine the gas-phase absolute shifts to compare to Eq. (30). The shifts of all of the peaks were relative to liquid-phase TMS which has an experimental absolute resonance shift of -31.5 ppm relative to the proton's gyromagnetic frequency [38-39]. Thus, the experimental shift of H_2 in $CDCl_3$ of 4.63 ppm relative to liquid-phase TMS corresponds to an absolute resonance shift of -26.87 ppm (-31.5 ppm + 4.63 ppm). Using the absolute H_2 gas-phase resonance shift of -28.0 ppm corresponding to 3.5 ppm (-28.0 ppm - 31.5 ppm) relative to liquid TMS, the $CDCl_3$ solvent effect is 1.13 ppm (4.63 ppm - 3.5 ppm) which is comparable to that of hydrocarbons [50].

 ^{1}H NMR spectra on sealed samples of condensable helium-hydrogen plasma gases dissolved in $CDCl_{3}$ relative to tetramethylsilane (TMS) are shown in Figure 16 (a)-(f). The solvent peak was observed at 7.26 ppm, the H_{2} peak was observed at 4.63 ppm, and a singlet at 3.22 ppm matched silane. Small ^{29}Si side bands were observed for the latter. The source was determined to be hydrogen-plasma reduction of the quartz tube. The peak was unchanged after three weeks at room temperature. No other silanes, silane decomposition species, or solvent decomposition species were observed after one month of repeat NMR analysis. Since the plasma gases were first passed through an LN trap before the plasma cell, and the cryotrap was high-vacuum (10^{-6} Torr) capable, no hydrocarbons were anticipated. This was confirmed by mass spectroscopic and FTIR analysis that showed only water vapor as a contaminant. Again, the source was determined to be hydrogen-plasma reduction of the quartz tube.

As further shown in Figures 16 (a)-(f), singlet peaks upfield of H_2 were observed at 3.47, 2.18, 1.47, 0.85, 0.21, and -1.8 ppm relative to TMS corresponding to solvent-corrected absolute resonance shifts of -29.16, -30.45, -31.16, -31.78, -32.42, and -34.43 ppm, respectively. Using Eq. (30), the data indicates that p = 2, 4, 5, 6, 7, and 10, respectively. The data matched the series $H_2(1/2)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, $H_2(1/7)$, and $H_2(1/10)$.

The observed series and the absence of $H_2(1/3)$ has implications for the catalysis reactions and the corresponding rates. The second ionization energy of helium is 54.4 eV; thus,

the ionization reaction of He^+ to He^{2+} has a net enthalpy of reaction of 54.4 eV which is equivalent to $2 \cdot 27.2 \, eV$. Since the products of the catalysis reaction have binding energies of $m \cdot 27.2 \, eV$, they may further serve as catalysts by so called exothermic disproportionation reactions where one atom goes to a lower state while another goes to a higher state [2-3]. Extreme ultraviolet (EUV) spectroscopy was recorded on microwave discharges of helium with 2% hydrogen. Novel emission lines were observed with energies of $q \cdot 13.6 \, eV$, q = 1,2,3,7,9,11 or $q \cdot 13.6 \, eV$, q = 4,6,8 less $21.2 \, eV$ corresponding to inelastic scattering of these photons by helium atoms due to excitation of $He(1s^2)$ to $He(1s^12p^1)$. Alternatively, the photon emission of the intermediate formed by resonant nonradiative energy transfer to the catalyst He^+ is partially quenched by the strong $He(1s^2)$ to $He(1s^12p^1)$ transition [40-41]. As given previously [40-41], the quenching reaction is selection rule dependent and results in the emission of a photon less energetic by $21.2 \, eV$. Thus, helium ion catalyzes $H[a_H]$ to $H\begin{bmatrix} a_H \\ 3 \end{bmatrix}$ as shown

in Eqs. (5-7) of Ref. [3]. Further disproportionation reactions may then proceed:

$$H\left[\frac{a_H}{3}\right] + H\left[\frac{a_H}{3}\right] \to H\left[\frac{a_H}{4}\right] + H\left[\frac{a_H}{2}\right] + 27.2 \text{ eV}$$
(37)

The observed, strong 45.6 nm emission [1-4, 26] indicates that the reaction rate for Eq. (37) is very high. Thus, species corresponding to the product atoms such as $H_2(1/2)$ and $H_2(1/4)$ with products from further transitions having p > 4 as given in Refs. [2-3] may dominate the reaction products.

The results of the ${}^{1}H$ NMR spectra recorded at China Lake on ultrahigh purity hydrogen and gases from the thermal decomposition of KH*I dissolved in $CDCl_3$ relative to tetramethylsilane (TMS) are shown in Figures 17 and 18, respectively. Results matching those shown in Figures 17 and 18 were obtained at BlackLight Power, Inc. In addition, these samples were determined not to contain hydrocarbons by mass spectroscopy and FTIR analysis. The closest possible peak to H_2O in Figure 18 is at 1.41 ppm; however, the assignment has some difficulty since the control (Figure 17) and literature [50] values put the H_2O peak at 1.57 ppm rather than 1.41 ppm and the peak is expected to be much broader as shown in the control (Figure 17). Excessive H_2O contamination may form a separate phase in $CDCl_3$, but the shift is downfield and the peak further broadens. In controls of 1% D_2O in $CDCl_3$, a very broad H_2O peak was observed at 4.79 ppm which matches the literature value [50].

Considering solvent effects, singlet peaks upfield of H_2 were observed from the KH*I-derived sample at 3.03, 2.18, 1.47, 0.85, and 0.22 ppm. From Eq. (30), the series matched the consecutive series $H_2(1/3)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, and $H_2(1/7)$, respectively. The observed products were consistent with those anticipated with the catalysis of H by K to form H(1/4) and subsequent disproportionation reactions [2-3, 18, 20, 9].

As shown in Figures 16 and 18, the observation of the combined series of singlet peaks upfield of H_2 with a predicted integer spacing of 0.64 ppm at 3.47, 3.03, 2.18, 1.47, 0.85, and 0.22 ppm identified as the consecutive series $H_2(1/2)$, $H_2(1/3)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, and $H_2(1/7)$ and $H_2(1/10)$ at -1.8 ppm provides powerful confirmation of the existence of $H_2(1/p)$. Furthermore, the ¹H NMR spectra of gases from the thermal decomposition of KH^*1 matched those of LN-condensable hydrogen. This provides strong support that compounds such as KH^*1 contain hydride ions $H^-(1/p)$ in the same fractional quantum state p as the corresponding observed $H_2(1/p)$. Observational agreement with predicted positions of upfield-shifted ¹H MAS NMR peaks (Eq. (31)) of the compounds [9, 20, 28-30], catalyst reactions [18, 20, 22-23], and spectroscopic data [18] supports this conclusion. On this basis, possibilities for advanced technologies are discussed in Sec. IIIBe.

d. Power Balance of the Helium-Hydrogen Microwave Plasma

The water bath calorimeter is an absolute standard and indicated $P_{in} = 41.9 \pm 1 \, W$ input power at the selected diode settings for all control plasmas. From these results, power input to the helium-hydrogen plasma was confidently known as the diode readings were identically matched for the controls. For example, the T(t) water bath response to stirring and then with selected panel meter readings of the constant forward and reflected microwave input power to krypton was recorded as shown in Figure 19. Using the corresponding T(t) in Eq. (34), the microwave input power was determined to be $41.9 \pm 1 \, \text{W}$. The T(t) response was significantly increased for helium-hydrogen (95/5%) as shown in Figure 19. From the difference in the T(t) water bath response, the output and excess power of the helium-hydrogen plasma reaction was determined to be $62.1 \pm 1 \, \text{W}$ and $20.2 \pm 1 \, \text{W}$ using Eq. (34) and Eq. (33) with the measured $P_{in} = 41.9 \pm 1 \, W$. The sources of error were the error in the calibration curve ($\pm 0.05 \, \text{W}$) and the measured microwave input power ($\pm 1 \, \text{W}$). The propagated error of the calibration and power measurements was $\pm 1 \, \text{W}$. Given an excess power of 20.2 W in 3 cm³ and a helium-hydrogen (95/5%) flow rate of 10.0 sccm, the excess power density and energy balance were high, $6.7 \, W/cm^3$ and $-5.4 \, X \, 10^4 \, kJ/mole \, H_2 \, (280 \, eV/H \, atom)$, respectively.

In addition to high energy spectral emission as shown in Sec. IIIA and previously [1-5], other indications of very energetic reactions are observed. For example, population inversion has been observed from plasmas which contain atomic hydrogen with the presence of a catalyst [22-25], and selective H broadening with a microwave plasma having no high DC field present was reported previously [14-16]. Microwave He/H_2 and Ar/H_2 plasmas showed extraordinary broadening corresponding to an average hydrogen atom temperature of $180-210 \, eV$ and $110-130 \, eV$, respectively. Whereas, pure hydrogen and Xe/H_2 microwave plasmas showed no excessive broadening corresponding to an average hydrogen atom temperature of $< 2 \, eV$ [14-

. . . .

16]. Only the H lines were Doppler broadened, and this result was shown to be inexplicable by any mechanism based on electric field acceleration of charged species. The observation of excessive Balmer line broadening in microwave driven plasmas as well as other hydrogen-mixed plasmas maintained in glow discharge [11-15] and RF discharge cells [15, 17] as well as unique chemically driven plasmas called resonant-transfer or rt-plasmas [18, 20, 22-23] requires a source of energy other than that provided by the electric field. The formation of fast H only in specific predicted plasmas was explained by a resonant energy transfer between hydrogen atoms and catalysts such as Ar^+ or He^+ of an integer multiple of the potential energy of atomic hydrogen, 27.2 eV [14-16]. Consistent with predictions, noncatalyst plasma mixtures such as Kr/H_2 and Xe/H_2 show no unique features. The observation of the $H_2(1/4)$ rotational lines reported in Sec. IIIAb from Ar/H_2 plasmas but not from Kr/H_2 and Xe/H_2 plasmas also matches predictions.

e. Applications

The existence of novel alkaline and alkaline earth hydride and halido-hydrides were previously identified by large distinct upfield 1H NMR resonances compared to the NMR peaks of the corresponding ordinary hydrides [20, 28-30]. Using a number of analytical techniques such as XPS and time-of-flight-secondary-mass-spectroscopy (ToF-SIMS) as well as NMR, the hydrogen content was assigned to $H^-(1/p)$, novel high-binding-energy hydride ions in stable fractional principal quantum states [9, 20, 28-30]. The upfield shifts of the novel hydride compounds matched those predicted for $H^-(1/2)$ and $H^-(1/4)$ (Eq. (31)). Novel spectral emission from $H^-(1/2)$ and $H^-(1/4)$, the predicted products from the potassium catalyst reaction and the supporting results of 1.) the formation of an intense hydrogen plasma chemically without an electric field or power input other than thermal [21], 2.) a high positive net enthalpy of reaction [20], 3.) characteristic predicted catalyst emission [18, 22-23], 4.) ~15 eV Doppler broadening of the Balmer lines [18, 22-23], and 5.) inversion of the Lyman lines [22-23] have also been reported previously.

Hydride ions with increased binding energies form novel compounds with potential for future applications in many industries including chemical, electronics, computer, military, energy, and aerospace in the form of products such as battery materials, propellants, solid fuels, surface coatings, structural materials, and chemical processes. The previously derived equation [8, 18] for the hydride binding energies E_B is

 $E_{B} = \frac{\hbar^{2} \sqrt{s(s+1)}}{8\mu_{e} a_{0}^{2} \left[\frac{1 + \sqrt{s(s+1)}}{p} \right]^{2}} - \frac{\pi \mu_{0} e^{2} \hbar^{2}}{m_{e}^{2}} \left[\frac{1}{a_{H}^{3}} + \frac{2^{2}}{a_{0}^{3} \left[\frac{1 + \sqrt{s(s+1)}}{p} \right]^{3}} \right]$ (38)

where p is an integer greater than one, s = 1/2, μ_o is the permeability of vacuum, and μ_e is the reduced electron mass given by $\mu_e = \frac{m_e m_p}{\frac{m_e}{4} + m_p}$ where m_p is the mass of the proton. The ionic

radius is

$$r_1 = \frac{a_0}{p} \left(1 + \sqrt{s(s+1)} \right) s = \frac{1}{2}$$
 (39)

From Eq. (38), the calculated ionization energy of the hydride ion is 0.75418 eV. The experimental value given by Lykke [53] is $6082.99 \pm 0.15 \, cm^{-1}$ (0.75418 eV). From Eq. (39), the radius of the hydride ion $H^-(1/p)$, p = integer is $\frac{1}{p}$ that of ordinary hydride ion, H^- . As shown in Table 2, the binding energies go through a maximum stability at p = 16 and decrease in stability such that p = 24 corresponds to the last stable ion of the series. Applications are anticipated based on this range of stability. Significant applications also exist for the corresponding molecular species $H_2(1/p)$.

i. High Voltage Battery

Hydride ions having extraordinary binding energies may stabilize a cation M^{x+} in an extraordinarily high oxidation state such as +2 in the case of lithium. Thus, these hydride ions may be used as the basis of a high voltage battery of a rocking chair design wherein the hydride ion moves back and forth between the cathode and anode half cells during discharge and charge cycles. Exemplary reactions for a cation M^{x+} are:

Cathode reaction:

$$MH_x + e^- \to MH_{x-1} + H^- \tag{40}$$

Anode reaction:

$$MH_{x-2} + H^{-} \to MH_{x-1} + e^{-}$$
 (41)

Overall reaction:

$$MH_x + MH_{x-2} \rightarrow 2MH_{x-1} \tag{42}$$

ii. Energetic Propellant

The reaction to form $H_2(1/p)$ from a hydride compound $M^+H^-(1/p)$ containing $H^-(1/p)$ where M^+ is a metal ion such as Li^+ and $p \approx 24$ represents a potentially very energetic reaction. In the application of $M^+H^-(1/p)$ as a solid, liquid, or gaseous rocket fuel, rocket propellant power may be provided by reaction of $M^+H^-(1/p)$ with a proton to form $H_2(1/p)$ or by the thermal decomposition of $M^+H^-(1/p)$ to form $H_2(1/p)^1$. The total energy of $H_2(1/p)$ and $H^-(1/p)$ are given by Eqs. (5) and (38), respectively. Using $32p^2 eV$ as an estimate of the total energy of $H_2(1/p)$ and the total energy of H(1/p) given by Eqs. (2a) and (2c) as an estimate of total energy of $H^-(1/p)$, the energy balance of the proton reaction is

$$M^{+}H^{-}(1/p) + H^{+}X^{-} \rightarrow H_{2}(1/p) + MX + p^{2}(32 - 13.6) eV$$
 (43)

The energy of the decomposition reaction is

$$2M^{+}H^{-}(1/p) \xrightarrow{\Delta} H_{2}(1/p) + 2M + p^{2}(32 - 2 \cdot 13.6) eV$$
 (44)

Very high energy balances are possible as p approaches the limit for a stable hydride ion at 24. In the case of $H^-(1/24)$, the energy balances for Eqs. (43) and (44) are truly unconventional, 10 keV and 2.7 keV, respectively. The mass of the reactants of Eqs. (43) and (44) may be comparable to those of hydrogen combustion that releases 1.48 eV per hydrogen atom; thus, energies of about 7000 and 2000 times that of the conventional hydrogen-oxygen reaction, respectively, are expected. Thus, a $H^-(1/24)$ -based propellant may be transformational especially given the logarithmic dependence on fuel-weight to lift in the rocketry equation [54].

iii. UV Laser

The existence of excited vibration-rotational levels of $H_2(1/p)$ presents the possibility of a laser using transitions between levels other than one to a state with both v, and J=0 A laser may be realized using standard cavities and mirrors that are appropriate for the desired wavelength similar to those of current lasers based on molecular vibration-rotational levels such as the CO_2 laser. However, an advantage exists to produce laser light at much shorter wavelengths. Based on the current results, a laser based on vibration-rotational levels of $H_2(1/4)$ could lase in the UV which has a significant application in photolithography.

IV. Conclusion

In this study we make specific theoretical predictions and test them with standard, easily interpretable experiments. The results show that the possibility that a novel reaction of atomic

¹ The helium-hydrogen microwave plasma contains H^+ which favors the reaction product $H_2(1/p)$ over $H^-(1/p)$ due to the highly exothermic reaction of Eq. (43) wherein X^- is a plasma electron or ordinary hydride ion. HeH(1/2) is also not favored due to the highly exothermic reaction to form $H_2(1/2)$.

hydrogen that uses certain catalysts such as He^+ , Ar^+ , and K may be a clean new energy source is supported by spectroscopic, chemical, and thermal data. For example, we report the discovery of new states of hydrogen formed in a catalytic plasma reaction. The atomic states H(1/p) were identified previously [1-4] by the spectroscopic observation of emission lines occurring at energies that are an extension of the Rydberg series to lower states. A corresponding molecular ion $H_2(1/4)^+$ and molecule $H_2(1/4)$ were identified by vibrational-rotational series that established an internuclear distance of 1/4 that of the ordinary hydrogen species. The molecular hydrogen gas product was isolated by liquefaction at liquid nitrogen temperature and by decomposition of compounds previously found to contain the corresponding hydride ions $H^{-}(1/p)$ [9, 20, 28-30]. Singlet peaks upfield of H_2 with a predicted integer spacing of 0.64 ppm at 3.47, 3.03, 2.18, 1.47, 0.85, and 0.22 ppm identified as the consecutive series $H_2(1/2)$, $H_2(1/3)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, and $H_2(1/7)$ and $H_2(1/10)$ at -1.8 ppm provides powerful confirmation of the existence of $H_2(1/p)$. Furthermore, the 'H NMR spectra of gases from the thermal decomposition of KH*I matched those of LN-condensable hydrogen which provides strong support that compounds such as KH * I contain hydride ions $H^-(1/p)$ in the same fractional quantum state p as the observed $H_2(1/p)$. Observational agreement with predicted positions of upfield-shifted ¹H MAS NMR peaks (Eq. (31)) of the compounds, catalyst reactions, and spectroscopic data supports this conclusion. On this basis, possibilities for advanced technologies are considered.

It was reported previously that stationary H populations were formed by using certain catalysts in hydrogen plasmas, and novel processes and hydride products with significant commercial potential were characterized by EUV and visible spectroscopy, NMR, ToF-SIMS, and XPS. Very high (>100 eV) H energies and substantial excess thermal energy were observed [14-16, 4, 26]. Using water bath calorimetry in this study, excess power was observed from the helium-hydrogen plasma compared to control krypton plasma. For example, for an input of 41.9 W, the total plasma power of the helium-hydrogen plasma measured by water bath calorimetry was 62.1 W corresponding to 20.2 W of excess power in 3 cm^3 . The excess power density and energy balance were high, $6.7 W/cm^3$ and $-5.4 \times 10^4 kJ/mole H_2$ (280 eV/H atom), respectively. The reaction of hydrogen to form water which releases $-241.8 kJ/mole H_2$ (1.48 eV/H atom) is about 200 times less than that observed. The results indicate that a new power source based on the catalysis of atomic hydrogen is not only possible, but it may be competitive with gas turbine combustion.

Based on their stability characteristics, advanced hydride technologies are indicated. Hydride ions $H^-(1/p)$ having extraordinary binding energies may stabilize a cation M^{x+} in an extraordinarily high oxidation state as the basis of a high voltage battery. And, a rocketry propellant based on $H^-(1/24)$ to $H_2(1/24)$ may be possible with an energy release so large that

it may be transformational. Significant applications also exist for the corresponding molecular species $H_2(1/p)$. The results of this study indicate that excited vibration-rotational levels of $H_2(1/4)$ could be the basis of a UV laser that could significantly advance photolithography.

b from Eq. (38)

Figure 1. Microwave plasma system and liquid nitrogen trap system for condensing gases from helium-hydrogen microwave plasmas maintained in an Evenson cavity. The experimental setup comprised a welded-joint stainless steel tubing system (1.27 cm OD X 165 cm length), two mass-flow controllers, two cryotraps, the quartz plasma cell (1.27 cm OD x 31 cm length), ion and TC vacuum gauges (SenTorr, Varian), six bellows valves (welded construction, Nupro Useries, helium leak tested to 4×10^{-9} sccm), and a turbo-molecular pump.

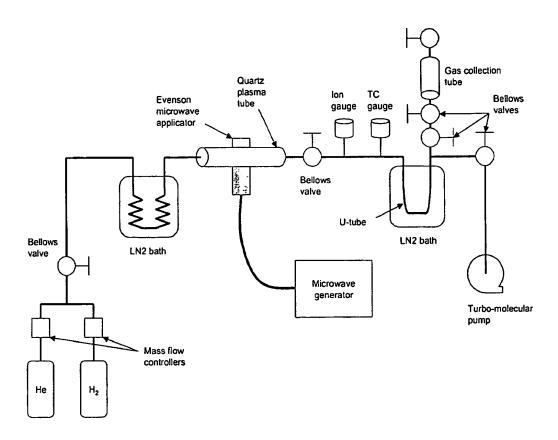

Figure 2. Microwave plasma system and cryo-cooler trap system maintained at ~12-17 K for condensing gases from helium-hydrogen microwave plasmas maintained in an Evenson cavity. The experimental setup comprised a welded-joint stainless steel tubing system, a metering valve, two LN cryotraps, the quartz plasma cell (1.27 cm OD x 31 cm length), a Baratron vacuum gauge, four bellows valves (Nupro B-series, helium leak tested to 4×10^{-9} sccm), a cryo-cooler compressor, a cryohead, a copper capillary tube (0.88 mm ID X 1.7 m length) spiraled on the cold stage of the cryo-head in an evacuated cylindrical chamber, a cryogenic silicon diode temperature sensor, and a turbo-molecular pump.

Gas Collection System

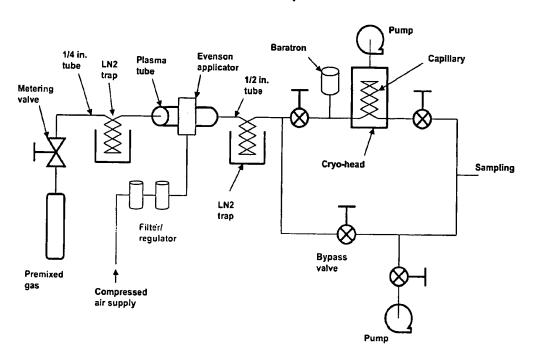

Figure 3. Schematic of the water bath calorimeter. The Evenson cavity and a plasma-containing section of the quartz tube were fitted with a water-tight stainless steel housing, and the housing and cell assembly were suspended by 4 support rods from an acrylic plate which held the cell vertically from the top of a water bath calorimeter.

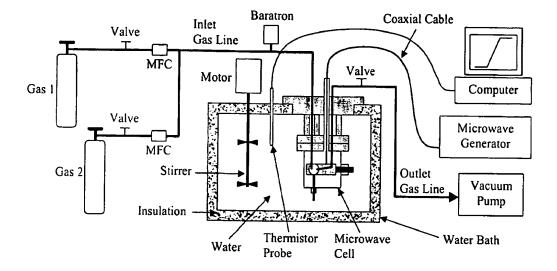

Figure 4. The EUV spectra (20-65 nm) of microwave plasmas of xenon and 10% hydrogen mixed with helium, krypton, and xenon. A vibrational pattern of peaks with an energy spacing of 1.18 eV was observed from the helium-hydrogen plasma having He^+ catalyst. The peaks matched Eq. (25) for $v^* = 0,1,2,3...24$. The series terminates at about 25.7 nm corresponding to the predicted bond energy of $H_2(1/4)^+$ of 48.16 eV given by Eq. (8). No emission was observed from the noncatalyst controls, krypton and xenon alone or with hydrogen. The sharp peaks in the spectrum were assigned to He I and He II.

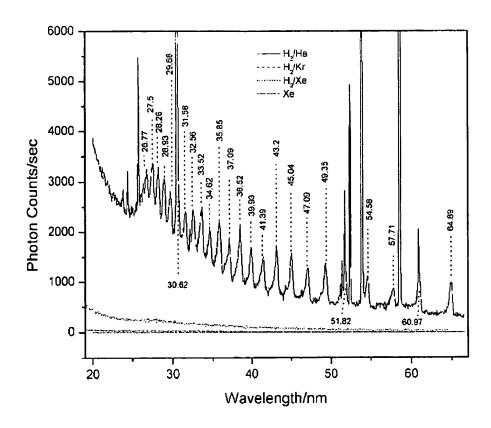

Figure 5. The EUV spectra (20-65 nm) of microwave plasmas of helium-hydrogen (90/10%) (solid) and helium alone (dashed). The vibrational series of peaks assigned to the reaction $H(1/4) + H^{+} \rightarrow H_{2}(1/4)^{+}$ was observed from the helium-hydrogen plasma having He^{+} catalyst and hydrogen, but not from helium alone. The sharp peaks in the spectrum were assigned to He and He II.

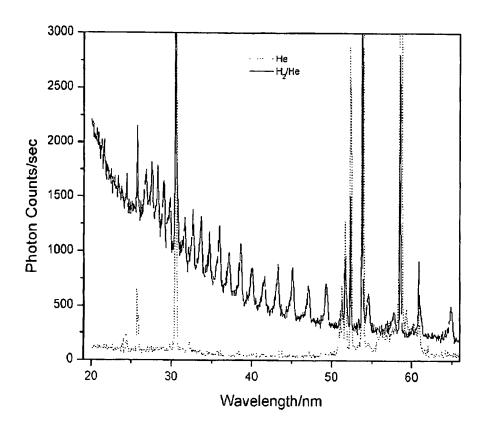

Figure 6. The plot of the energies of the peaks shown in Figures 4 and 5. The slope of the linear curve fit is 1.18 eV, and the intercept is 47.6 eV which matches the predicted emission given by Eq. (25) to within the spectrometer resolution of about 1%.

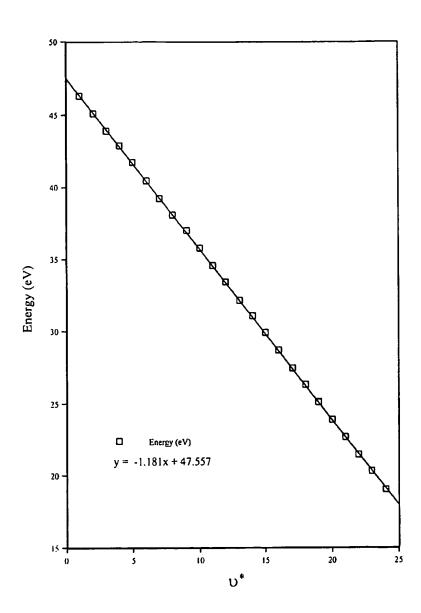

Figure 7. The EUV spectra (20-65 nm) of microwave plasmas of argon-hydrogen (90/10%) (solid) and argon alone (dashed). The vibrational series of peaks assigned to the reaction $H(1/4) + H^+ \rightarrow H_2(1/4)^+$ was observed from the argon-hydrogen plasma having Ar^+ catalyst and hydrogen, but not from argon alone. The sharp peaks in the spectrum were assigned to Ar I and Ar II.

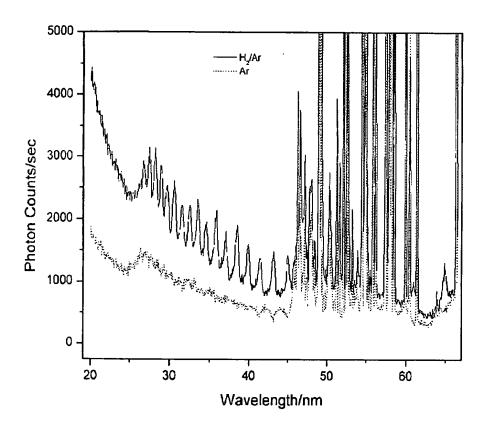

Figure 8. The 100-350 nm spectrum of a 783 Torr plasma of argon containing about 1% hydrogen and oxygen. Lyman α was observed at 121.6 nm with an adjoining H_2 band, the third continuum of Ar was observed at 210 nm, and the OH(A-X) bands were observed at 282.7 and 308.6 nm. A series of sharp, evenly-spaced lines was observed in the region 145-185 nm. The series matched the P branch of $H_2(1/4)$ for the vibrational transition $\upsilon=1 \rightarrow \upsilon=0$. P(1), P(2), P(3), P(4), P(5), and P(6) were observed at 154.94 nm, 159.74 nm, 165.54 nm, 171.24 nm, 178.14 nm, and 183.14 nm, respectively. The sharp peak at 146.84 nm may be the first member of the R branch, R(1). The R-branch lines appeared to correspond to forbidden transitions, or the emission was suppressed by the argon second continuum.

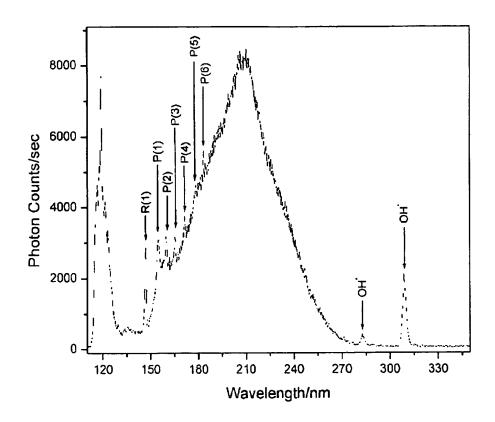

Figure 9. The plot of the energies of the peaks shown in Figure 8. The slope of the linear curve fit is 0.245 eV with an intercept of 8.25 eV which matches Eq. (27) very well for p = 4. The series matches the predicted $v = 1 \rightarrow v = 0$ vibrational energy of $H_2(1/4)$ of 8.224 eV (Eq. (14)) and its predicted rotational energy spacing of 0.241 eV (Eq. (20)) with $\Delta J = +1$; J = 0,1,2,3,4,5.

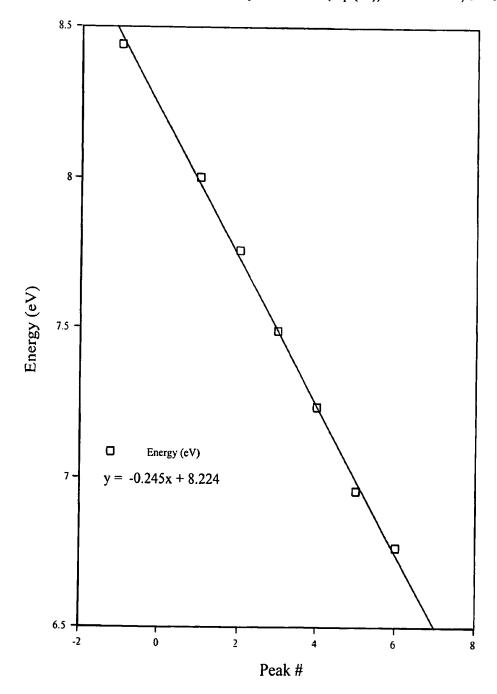

Figure 10. The 100-350 nm spectrum of a 456 Torr plasma of argon containing about 1% hydrogen and nitrogen. Lyman α was observed at 121.6 nm, the third continuum of Ar was observed at 190 nm, and background molecular emission was observed including $N_2 C^3 \Pi_u - B^3 \Pi_g$ emission in the 270-350 region. A series of sharp, evenly-spaced lines was observed in the region 200-275 nm. The series matched the P branch of $H_2(1/4)$ for the vibrational transition $\nu = 5 \rightarrow \nu = 4$. P(1), P(2), P(3), P(4), P(5), P(6), and P(7) were observed at 204.94 nm, 215.04 nm, 226.44 nm, 236.44 nm, 247.14 nm, 258.74, and 271.34 nm, respectively. The R-branch lines appeared to correspond to forbidden transitions, or the emission was suppressed by the argon third continuum.

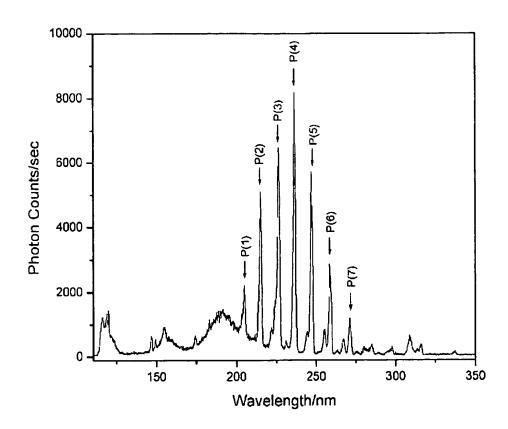

Figure 11. The plot of the energies of the peaks shown in Figure 10. The slope of the linear curve fit is 0.245 eV with an intercept at 6.25 eV which matches Eq. (27) very well for p = 4. The series matches the predicted $v = 5 \rightarrow v = 4$ vibrational energy of $H_2(1/4)$ of 6.30 eV (Eq. (14)) and its predicted rotational energy spacing of 0.241 eV (Eq. (20)) with $\Delta J = +1$; J = 0,1,2,3,4,5,6.

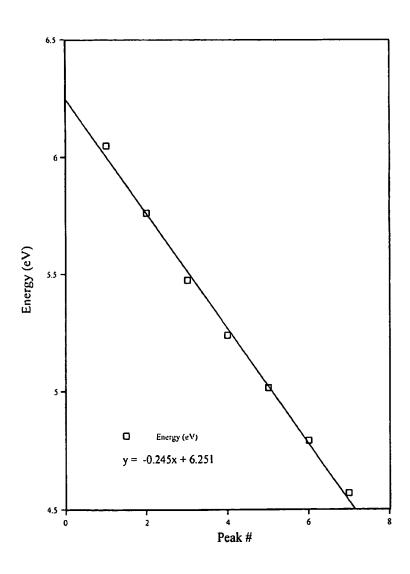

Figure 12. Comparison of the third continuum of argon gas as recorded by Ulrich, Wieser, and Murnick [41] with a very pure gas (upper spectrum) and a spectrum in which the gas was slightly contaminated by oxygen as evidenced by the second order of the 130 nm resonance lines at 160 nm. A series of narrow, evenly-spaced lines that appear similar to those in Figures 8 and 10 were observed that could not be assigned by Ulrich et al. to known species. The determination of the presence of hydrogen is warranted in future studies.

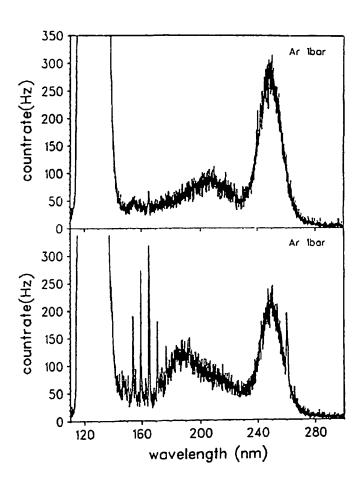

Figure 13. The pressure as a function of time after the liquid nitrogen dewar was removed from the U-tube cryotrap following 2 hours of helium-hydrogen (90/10%) gas flow through the microwave tube and the cryosystem shown in Figure 1 without plasma (dotted) and with a plasma maintained with 60 W forward microwave power and 10 W reflected (solid). A liquid-nitrogen condensable gas product was only observed for the plasma reaction run.

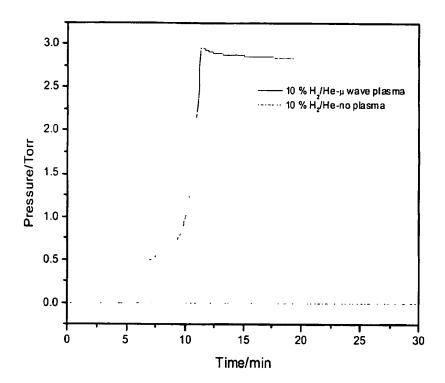

Figure 14. The mass spectra (m/e=1 to m/e=50) for the gases collected from He/H_2 (90/10%) microwave plasmas (IP =70 eV). (a) The mass spectrum of the gas condensed by the LN cryotrap over 2 hours. Only hydrogen peaks were observed which identified the liquid-nitrogen-condensable gas as hydrogen. (b) The mass spectrum of plasma gas collected by the cryo-cooler. The m/e=2 peak was 40-50 times more intense than the m/e=28 and m/e=32 peaks that were assigned to very trace residual air contamination. When corrected for ionization efficiency, H_2 (m/e=2) was determined to be ~500 times more abundant than the background.

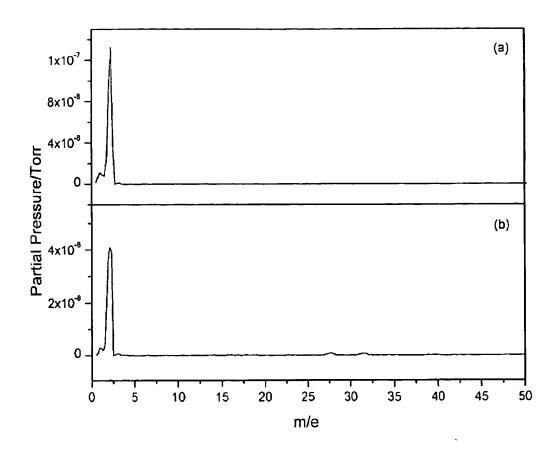

Figure 15. The phase diagram of hydrogen and helium. Since it is not possible to condense ordinary hydrogen below ~ 50 Torr at 12-17 K, the m/e = 2 peak of the mass spectrum (Figure 14) of plasma gas collected by the cryo-cooler at 700 mTorr that was not removed at 10^{-5} Torr indicates that a novel hydrogen gas formed in the plasma reaction between hydrogen and helium.

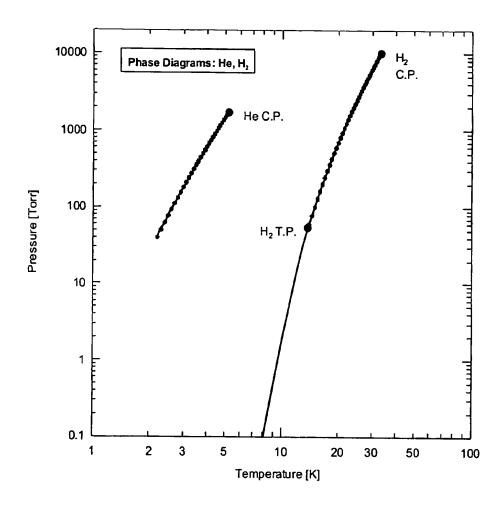

Figure 16 (a)-(f). ^{1}H NMR spectra on scaled samples of liquid-nitrogen-condensable helium-hydrogen plasma gases dissolved in $CDCl_3$ relative to tetramethylsilane (TMS). The solvent peak was observed at 7.26 ppm, the H_2 was observed at 4.63 ppm, and a singlet at 3.22 ppm matched silane. Singlet peaks upfield of H_2 were observed at 3.47, 2.18, 1.47, 0.85, 0.21, and -1.8 ppm relative to TMS corresponding to solvent-corrected absolute resonance shifts of -29.16, -30.45, -31.16, -31.78, -32.42, and -34.43 ppm, respectively. Using Eq. (30), the data indicates that p = 2, 4, 5, 6, 7, and 10, respectively. The data matched the series $H_2(1/2)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, $H_2(1/7)$, and $H_2(1/10)$.

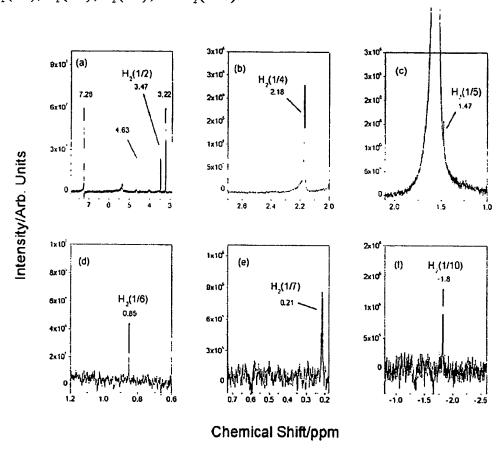

Figure 17. The ^{1}H NMR spectrum recorded at China Lake on a sealed sample of ultrahigh purity hydrogen dissolved in $CDCl_{3}$ relative to external tetramethylsilane (TMS). Singlet peaks were observed at 7.27, 4.63, and 1.56 ppm corresponding to $CHCl_{3}$, H_{2} , and $H_{2}O$, respectively.

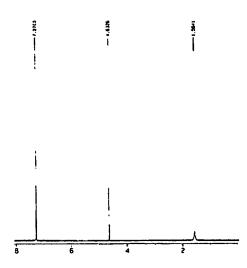

Figure 18. The ${}^{1}H$ NMR spectrum recorded at China Lake on gases from the thermal decomposition of KH * I dissolved in $CDCl_3$ relative to tetramethylsilane (TMS). H_2 was observed at 4.63 ppm. Considering solvent effects, singlet peaks upfield of H_2 were observed with a predicted integer spacing of 0.64 ppm at 3.03, 2.18, 1.47, 0.85, and 0.22 ppm which matched the consecutive series $H_2(1/3)$, $H_2(1/4)$, $H_2(1/5)$, $H_2(1/6)$, and $H_2(1/7)$, respectively.

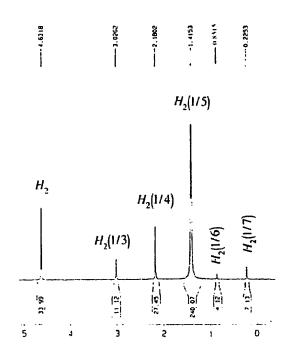

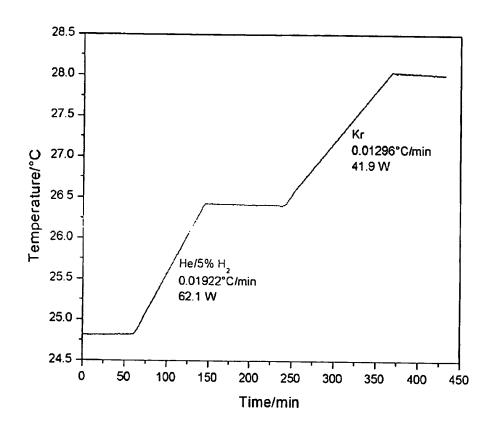

Figure 19. The T(t) water bath response to stirring and then with selected panel meter readings of the constant forward and reflected microwave input power to helium-hydrogen (95/5%) mixture was recorded. Krypton control was run at identical microwave input power readings, and the microwave input power was determined to be 41.9 ± 1 W. From the difference in the T(t) water bath response, the excess power of the helium-hydrogen plasma reaction was determined to be 20.2 ± 1 W.

The mobility of free electrons in oil increased by a factor of two as 10/7/01 indicated by the results of Kelly [Arnold J. Kelly, "Electrostatic Atomizing Device, United States Patent No. 4,581,675, April 8, 1986]. Above breakdown, the slope of the current versus electric field was discontinuous. It shifted to one half that before breakdown. This corresponds to a higher mobility of electrons to the grounded electrode of a triode, with a concomitant reduction in charging of the moving oil and the corresponding charged fluid current at the outlet of the dispersion device of Kelly. The breakdown current proves light which excites the electron transition from the n=1 to the n=1/2 state as described by Mills [R. Mills, The Nature of Free Electrons in Superfluid Helium--a Test of Quantum Mechanics and a Basis to Review its Foundations and Make a Comparison to Classical Theory, Int. J. Hydrogen Energy, Vol. 26, No. 10, (2001), pp. 1059-1096]. Excitation of electrons to fractional states is a method to increase their mobility to more effectively charge a fluid in order to form a dispersed fluid. The apparatus taught by Kelly [Arnold J. Kelly, "Electrostatic Atomizing Device, United States Patent No. 4,581,675, April 8, 1986] may be improved by a modification to include a source of light to cause the electron transitions as taught by Mills [R. Mills, The Nature of Free Electrons in Superfluid Helium--a Test of Quantum Mechanics and a Basis to Review its Foundations and Make a Comparison to Classical Theory, Int. J. Hydrogen Energy, Vol. 26, No. 10, (2001), pp. 1059-1096].

In another embodiment of an apparatus, methods, and compounds terminated or comprising lower-energy hydrogen of the present invention disclosed in my Provisional U.S. Patent Application entitled "Diamond Synthesis", filed on May 1, 2002, a source of carbon in replaced by a source of any Group IV element such as silicon, germanium, tin or lead. Solid, liquid, and gaseous sources of Group IV elements are given in David R. Linde, CRC Handbook of Chemistry and Physics, 79 th Edition, CRC Press, Boca Raton, Florida, (1998-1999), p. 4-82 to 4-83, 4-59, 4-91 to 4-92, 4-65 to 4-66 which is herein incorporated by reference. Sources of carbon of the present invention are also given by Linde at 3-3 to 3-330 and 4-49 to 4-50 which is herein incorporated by reference in its entirety.

In an embodiment, of the microwave power cell and hydrino hydride reactor, the output power is optimized by using a cavity such as an Evenson cavity and tuning the cell to an optimal voltage staging wave. In an embodiment, the reflected versus input power is tuned such that a desired voltage standing wave is obtained which optimizes or controls the Typically, the ratio of the maximum voltage to the output power. minimum voltage on the transmission line determines the voltage standing wave. In another embodiment, the cell comprises a tunable microwave cavity having a desired voltage standing wave to optimize and control the output power.

5/23/02

Metal hydride films such as FeH form with a neon-hydrogen (99/1%) plasma with a stainless steel reactor and a stainless steel cathode. Preferably the cathode is made of a metal M and MH is synthesized wherein H is an increased binding energy hydrogen species. embodiment, the cathode is iron in the case of the synthesis of FeH. another embodiment, the cell is operated at an elevated temperature. The cell may be operated in the temperature range of about 25-100°C. Preferably the cell is operated in the range of about 100-3500°C. preferably the cell is operated in the range of about 200-1500°C. Most preferably the cell is operated in the range of about 400-800°C. The higher operating temperature may also cause hydrino hydride compounds to volatilize from the cathode to increase the power of the hydrogen catalysis reaction by maintaining a high voltage, hollow cathode discharge as opposed to a lower voltage discharge at a constant input power.

5/16/02

new patent claiming use of ultrasound to force motion in the tissue to achieve resonance at a specific frequency and to produce a finite recoilless fraction. Rather than thermal and body motion causing a destruction of the resonance, drive a specific motion with ultrasound that suppresses the random motion in order to achieve the Mossbauer effect. Selectivity is also achieved since the corresponding resonance frequency may be induced only in the tissue of interest.

5/15/02 The synthesis of the metal hydride films requires lining the reactor with

The present invention of a power cell and power converter comprises a hydrogen catalysis cell that produces an inverted hydrogen population such as one of those disclosed in my US Provisional Patent Applications entitled "Blue Laser" filed on May 17, 2002 and June 6, 2002 which are herein incorporated by reference in their entirety. embodiment, the power cell comprises a hydrogen laser as further disclosed in my US Provisional Patent Applications entitled "Blue Laser" filed on May 17, 2002 and June 6, 2002. The laser light is converted to electricity using a photon-to-electric converter of the present invention such as a photoelectric or photovoltaic cell. In the case of a photoelectric cell, the photons are incident on a photoelectric material that is responsive to the wavelength of the laser light such that electrons are ejected and collected at a grid or electrode. The photoelectric material serves as a anode (positive electrode) and the electron collector serves as The electrical circuit completed between a cathode (negative electrode). these electrodes through a load such that the voltage developed between the electrodes drives a current. Thus, electrical power is delivered to and dissipated in the load.

These lines may be observed from argon-hydrogen plasma emission when oxygen was added. Run argon-hydrogen. Add oxygen since oxygen will also eliminate the molecular hydrogen peaks in this region. Alternatively, run argon-water vapor plasma. Repeat with helium and neon. The observation of vibration-rotational lines of $H_2(1/4)$ by electron beam excitation will support that the Franck-Hertz experiment will be successful.

*• Electron impact excitation may be possible with spectroscopy in the near-electrode region of a high voltage discharge. Record the vibration-rotational lines of $H_2(1/4)$ from glow discharge plasma of catalyst-hydrogen mixtures such as argon, helium, or neon mixed with hydrogen.

In the case that a high pressure noble catalyst-hydrogen mixture such as an argon-hydrogen mixture is used, the formation of a plasma with an electron beam may result in the formation of a high concentration of excimers such as Ar_2 *. The noble catalyst-hydrogen mixture may be maintained in the high pressure range of about 1 Torr to 100 atm, preferably in the range of about 10 Torr to 10 atm, more preferably in range of about 100 Torr to 5 atm, and most preferably in the range of about 300 Torr to 1 atm. In addition to the formation of the catalyst from a source by electron-beam ionization, a source of ionizing ion may be added to form the catalyst from the source of catalyst. In an embodiment, He^+ , Ne^+ , Ne^+/H^+ or Ar^+ catalysts are formed from a source comprising helium, neon, neon-hydrogen mixture, and argon gases, The ionizing ion may be ionized by means such as the electron beam and secondarily ionize the source of catalyst to form the catalyst. The ionizing ion may be O^+ from O_2 . The ionizing ion may react with noble gas excimers to form the catalyst. The excimers may be He₂*, Ne_2^* , Ne_2^* , and Ar_2^* , and the catalysts may be He^+ , Ne^+ , Ne^+/H^+ or Ar^+ , respectively.

In an embodiment, the ionization energy of the noble gas atom is higher than the energy released when the ionizing ion is reduced by ionizing the noble gas atom. The ionization of the noble gas atom occurs because the noble gas atom comprises an excimer in an excited state. excited state energy makes the ionization energetically favorable. embodiment, A_{7} * has an excited state energy of about 9-10 eV; thus, the ionization reaction 6/6/03

 $Ar_2 * + O^+ \rightarrow Ar + Ar^+ + O$

(1) is energetically favorable wherein the first ionization energies of Ar and O are 15.75962 and 13.61806 eV, respectively.

A number of experiments indicate that negatively charging the plasma or the reaction mixture will enhance the rate of the hydrogen catalysis reaction. The electrolysis cell that maintains a negative voltage when the power is switched off has a measured gain of at least 10 times The electron gun experiment shows a high yield of the input power. The rt-plasma has the greatest intensity when lower-energy hydrogen. the W filament is hot enough to emit electrons. N. Greenig discharge cell comprised a W filament anode which can emit electrons. The K2CO3 cell run by Conrads et al. used a W wire heated externally wherein the W wire may serve as a source of electrons. The Sr-H2 rt-plasma increased significantly with the application of magnetic electron confinement. Inversion, broadening, and lower-energy hydrogen emission is observed when the wall temperature of the cells maintaining plasmas of catalysts and hydrogen is elevated to boil off hydride ions. This was observed with the RF and Evenson cell plasmas maintained in quartz or Pyrex Excess heat was observed with an elevated wall temperature in the case of glow discharge cells wherein the elevated temperatures were maintained by an oven.

The negative charge may increase the rate by filling electron energy levels such those below the continuum level. The filling of the level up to the vacuum level may be analogous to the Fermi level of a metal. In this case, the net enthalpy of the catalyst provided by ionization of one or more electrons to the continuum level better matches an integer multiple of 27.2 eV.

In an embodiment of the hydrogen catalysis cell, the plasma has a net negative charge at least in a region where catalyst and atomic hydrogen is present. The negative charge may be provided by at least one of a source of electrons and a means to confine electrons. The means to confine electrons may be a magnetic field such as a magnetic bottle or a selenoidal field. The electron source may be an electron emitter such as a heated filament such as a thoriated W, rhenium, or BaO filament or an alkali (Group I) metal or an alkaline earth (Group II) metal. of electrons may be a thermionic cathode. The source of electrons may Alternatively, the source of electrons may be an BO be an electron gun. electron beam or a discharge electrode such as an anode. The electrons also may preferentially be increased in a desired spatial region by an electric The electric field may be provided by electrodes. The negative charge may also be provided by a source of negatively charged ions such as hydride ions. In an embodiment, negative ions such as hydride ions are boiled from the surface of the wall of the reactor by maintaining the wall at an elevated temperature.
